Spherical roller bearings have two rows of symmetrical rollers, a common sphered outer ring raceway and two inner ring raceways inclined at an angle to the bearing axis (**fig. 1**). The centre point of the sphere in the outer ring raceway is at the bearing axis.

## Bearing features

- **Accommodate misalignment**  
Spherical roller bearings are self-aligning like self-aligning ball bearings or CARB bearings (**fig. 2**).
- **High load carrying capacity**  
Spherical roller bearings are designed to accommodate both heavy radial loads and axial loads in both directions.

- **Long service life**  
The rollers are manufactured to such tight dimensional and geometrical tolerances that they are practically identical in a roller set. The symmetrical rollers self-adjust (**fig. 3**), providing optimal load distribution along the roller length and together with the special profile prevent stress peaks at the roller ends (**fig. 4**).
- **Low friction**  
Self-guiding rollers keep friction and frictional heat at low levels (**fig. 5**). A floating guide ring guides unloaded rollers so that they enter the load zone in the optimal position.
- **Robust**  
All SKF spherical roller bearings contain strong window- or prong-type cages.

## SKF standard assortment

The assortment of SKF spherical roller bearings is the widest available on the market. The standard assortment includes:

- CC, CA and E design bearings
- sealed bearings
- bearings for vibratory applications
- bearings for wind energy applications

All SKF spherical roller bearings are SKF Explorer bearings ([page 7](#)) and almost all bearings are available with the option of a tapered bore. Depending on the bearing series, the tapered bore has:

- a taper 1:12 (designation suffix K)
- a taper 1:30 (designation suffix K30)

For sizes and variants not listed in the product tables, contact SKF.

## CC, CA and E design bearings

### CC design bearings

- have two stamped window-type steel cages, an inner ring without flanges and a floating guide ring centred on the inner ring ([fig. 6](#))
- are indicated in the product table by the designation suffix C or CC
- are indicated in the product table by the designation suffix EC or ECC for larger bearings and have an optimized internal design for increased load carrying capacity

### CA design bearings

- have a machined double prong-type brass cage, an inner ring with a retaining flange on both sides and a floating guide ring centred on the inner ring ([fig. 6](#))
- The flanges on the inner ring are designed to keep the rollers in place when swivelling the bearing during mounting or maintenance and are not designed to guide the rollers or accommodate any axial load.

- are indicated in the product table by the designation suffix CA
- are indicated in the product table by the designation suffix ECA for larger bearings and have an optimized internal design for increased load carrying capacity

### E design bearings

- have two stamped window-type steel cages, an inner ring without flanges and a floating guide ring centred on the inner ring ( $d \leq 65$  mm) or on the cages ( $d > 65$  mm) ([fig. 6](#))
- are indicated in the product table by the designation suffix E
- have an optimized internal design for increased load carrying capacity

### Cages

For information about the suitability of cages, refer to Cages, [page 187](#).

## 9 Spherical roller bearings

### Annular groove and lubrication holes

- CC and CA design bearings are available with an annular groove and three lubrication holes in the outer ring (designation suffix W33) or three lubrication holes in the outer ring (designation suffix W20) (fig. 7).
- E design bearings have an annular groove and three lubrication holes as standard (fig. 6, page 775). This feature is not identified in the bearing designation (no designation suffix).

### Sealed bearings

- have the same features and internal design as open spherical roller bearings
- are available with a cylindrical bore as standard
- are supplied grease lubricated and should not be washed
- are equipped with an annular groove and three lubrication holes in the outer ring, except for those with the designation suffix W
- are fitted with a contact seal, on one or both sides, made of one of the following materials:
  - sheet steel reinforced NBR (designation suffix CS or RS)
  - sheet steel reinforced HNBR (designation suffix CS5 or RS5)
  - sheet steel reinforced FKM (designation suffix CS2)

The seals are fitted in a recess on the outer ring and seal against the inner ring (fig. 8). On larger bearings, the seals are fixed by a retaining ring (fig. 9).

Bearings sealed on both sides are lubricated for the life of the bearing and are virtually maintenance-free (*Grease life for sealed bearings*). They are filled with one of the following greases (table 1):

- SKF LGEP 2 grease (designation suffix VT143) as standard
- SKF LGHB 2 grease (designation suffix GEM9) or LGWM 2 grease (designation suffix GLE) on request

For additional information about greases, refer to *Selecting a suitable SKF grease*, page 116.

### Grease life for sealed bearings

The grease life for sealed bearings is presented as  $L_{10}$ , i.e. the time period at the end of which 90% of the bearings are still reliably lubricated, and depends on the load, operating temperature and speed value. It can be obtained for bearings with standard SKF LGEP 2 grease (designation suffix VT143) from:

- diagram 1, for light load ( $P \leq 0,067 C$ )
- diagram 2, page 778, for normal load ( $P \leq 0,125 C$ )

The grease life is valid under the following operating conditions:

- horizontal shaft
- inner ring rotation
- operating temperature within the green temperature zone of the grease (table 1)
- stationary machine
- low vibration levels
- load ratio  $F_a/F_r \leq e$  (product table, page 792)
- rotational speed below the limiting speed (product table) and below the limits listed in table 2, page 778

For other operating conditions, the grease life can be estimated by multiplying the relubrication interval for open bearings (*Estimating the relubrication interval for grease*, page 111) by a factor of 2,7.

## Relubrication of sealed bearings

When the required service life is longer than the grease life, the bearings may require relubrication. A suitable grease quantity to relubricate sealed bearings can be obtained using

$$G_p = 0,0015 D B$$

where

$G_p$  = grease quantity [g]

$D$  = bearing outside diameter [mm]

$B$  = bearing width [mm]

The grease should be applied slowly through the lubrication holes in the outer ring, preferably while the bearing is rotating to avoid damaging the seals. SKF recommends relubricating with the same grease as the initial fill.

### ⚠ WARNING

Seals made of FKM (fluoro rubber) exposed to an open flame or temperatures above 300 °C (570 °F) are a health and environmental hazard! They remain dangerous even after they have cooled.

Read and follow the safety precautions on [page 197](#).

## Bearings for vibratory applications

- are available in the 223 series
- are available with a cylindrical or tapered bore
- have C4 radial internal clearance as standard
- are equipped with an annular groove and three lubrication holes in the outer ring
- are available with a PTFE coated cylindrical bore (designation suffix VA406), which prevents fretting corrosion between the shaft and the bearing bore, for shaft thermal elongation in non-locating bearing positions that have a rotating outer ring load

Therefore, shafts do not require special heat treatments or coatings.

- are manufactured to one of the following designs (fig. 10):
  - E/VA405 bearings have two surface-hardened stamped window-type steel cages, an inner ring without flanges and a guide ring centred on the inner ring or on the cages.
  - EJA/VA405 and CCJA/W33VA405 bearings have two surface-hardened stamped window-type steel cages, an inner ring without flanges and a guide ring centred on the outer ring raceway.

## Acceleration

Vibratory applications induce accelerations of the rollers and cages in the bearings. This puts extra demands on the bearing design. SKF spherical roller bearings for vibratory applications can withstand considerably higher accelerations than corresponding standard bearings. The permissible acceleration depends on the lubricant and the mode of acceleration.

### • Mode 1

The bearing is subjected to a rotating outer ring load in combination with a rotating acceleration field, or an internally induced angular acceleration field caused by rapid speed variations. These accelerations cause the unloaded rollers to generate cyclic loads on the cages. Examples: vibrating screens (fig. 11), exciters, planetary gears and general arrangements subjected to rapid starts or rapid speed variations.

### • Mode 2

The bearing is subjected to impact loads, which generate a linear acceleration in a constant radial direction, causing the unloaded rollers to “hammer” the cage pockets. Example: acceleration generated when rail wheels roll over rail joints (fig. 12).

Road rollers, where the roller is vibrating against a relatively hard surface, are subjected to a combination of mode 1 and 2 acceleration. Values for the permissible acceleration are listed in the [product table](#), [page 792](#), and are valid for oil lubricated bearings. The values are expressed in multiples of  $g$ , where  $g$  is the acceleration of gravity ( $g = 9,81 \text{ m/s}^2$ ).

## System solutions for vibrating screens

In addition to single bearings for vibrating screens, SKF has developed fault detection and bearing arrangements that can improve performance, reduce maintenance and monitor machine condition in vibratory equipment.

### ⚠ WARNING

PTFE coatings exposed to an open flame or temperatures above 300 °C (570 °F) are a health and environmental hazard! They remain dangerous even after they have cooled.

Read and follow the safety precautions on [page 197](#).

# Bearings for wind energy applications

- are available in the 240 series, from  $d \geq 530$  mm
- are designed explicitly for wind turbine main shafts
- have an optimized internal geometry with large diameter rollers and increased contact angle for increased axial load carrying capacity (fig. 13)
- have a roller-guided cast iron cage for increased robustness
- have no guide ring
- have a wide outer ring lubrication groove and six lubrication holes
- are indicated in the product table, page 792, by the designation suffix BC

# Customized bearings

SKF can customize bearings to meet the needs of applications where the bearings are subjected to unique operating conditions. For example, bearings for:

- printing presses, paper mills or high-precision coating systems
- very arduous operating conditions, e.g. continuous casters
- bearings for high-speed applications
- mounting with loose fit on roll necks
- railway vehicles

# Bearings for high-speed applications

- have 50% higher limiting speeds than standard bearings
- are available in the 223, 232, 240 and 241 series in a special execution
- are identified by the designation suffix VA991
- address a market need in multi-megawatt industrial gearboxes

## Temperature limits

The permissible operating temperature for spherical roller bearings can be limited by:

- the dimensional stability of the bearing rings
- the seals
- the lubricant

Where temperatures outside the permissible range are expected, contact SKF.

### Bearing rings

SKF spherical roller bearings undergo a special heat treatment. The bearings are heat stabilized up to at least 200 °C (390 °F).

### Seals

The permissible operating temperature for seals depends on the seal material:

- NBR: -40 to +90 °C (-40 to +195 °F)  
Temperatures up to 120 °C (250 °F) can be tolerated for brief periods.
- HNBR: -40 to +150 °C (-40 to +300 °F)
- FKM: -30 to +200 °C (-20 to +390 °F)

Typically, temperature peaks are at the seal lip.

### Lubricants

Temperature limits for the greases used in sealed SKF spherical roller bearings are provided in [table 1, page 777](#). For temperature limits of other SKF greases, refer to *Selecting a suitable SKF grease*, [page 116](#).

When using lubricants not supplied by SKF, temperature limits should be evaluated according to the SKF traffic light concept ([page 117](#)).

## Permissible speed

The speed ratings in the [product table](#) indicate:

- the **reference speed**, which enables a quick assessment of the speed capabilities from a thermal frame of reference
- the **limiting speed**, which is a mechanical limit that should not be exceeded unless the bearing design and the application are adapted for higher speeds

For additional information, refer to *Operating temperature and speed*, [page 130](#).

# Design considerations

## Free space on both sides of the bearing

To prevent interference between rotating bearing parts and stationary machine parts, free space ( $C_a$ ) should be provided as indicated in [fig. 15](#). The requisite width of the free space depends on:

- the actual misalignment
- lubricant space requirements

The requisite free space should be at least 20 times the minimum value of the radial internal clearance in the unmounted bearing:

- with a cylindrical bore ([table 4, page 782](#))
- with a tapered bore ([table 5, page 783](#))

## Abutments for sealed bearings

The diameter of the shaft abutment should not exceed  $d_{a \max}$  ([product table, page 792](#)), certainly for the 1 to 2 mm closest to the bearing, to prevent interference with the seal ([fig. 16](#)). If the bearings are to be located axially on the shaft by a lock nut, SKF recommends using a KMFE lock nut ([fig. 17](#)) or fitting a spacer ring ([fig. 18](#)) between the bearing and the lock washer to prevent interference with the seal.

# Bearings on sleeves

Spherical roller bearings with a tapered bore can be mounted with:

- an adapter sleeve on plain or stepped shafts (fig. 19):
  - SKF adapter sleeves are supplied complete with a locking device.
  - Use appropriate SKF adapter sleeve assemblies for sealed bearings (fig. 20) to prevent the locking device interfering with the seal (product table, page 824). Alternatively, a spacer ring can be inserted between the bearing and the lock washer.
- a withdrawal sleeve on stepped shafts (fig. 21)

For additional information about sleeves, refer to **Adapter sleeves**, page 1065, and **Withdrawal sleeves**, page 1087.

# Appropriate bearing housings

The combination of a spherical roller bearing, appropriate sleeve (where needed), and an appropriate SKF bearing housing provides a cost-effective, interchangeable and reliable solution that fulfils the demand for easy maintenance.

The comprehensive assortment of SKF bearing housings is provided online at [skf.com/housings](http://skf.com/housings).

## Mounting

During handling, the rings and roller complement of spherical roller bearings may be axially displaced from their normal position. This is especially likely where the bearings are mounted with the shaft or housing in the vertical position:

- The roller complement, together with the inner or outer ring, will move downward and result in no more clearance.
- When the bearing rings expand or contract as a result of an interference fit, preload is likely to result.

Therefore, wherever possible:

- Mount spherical roller bearings with the shaft or housing in the horizontal position.
- Rotate the inner or outer ring to align the rollers during mounting.

Where this is not feasible, use a bearing handling tool or other device to keep the bearing components arranged centrally.

## Mounting sealed bearings

SKF does not recommend heating sealed spherical roller bearings above 80 °C (175 °F) during the mounting process. However, if higher temperatures are necessary, make sure that the temperature does not exceed the permissible temperature of either the seal or grease, whichever is the lowest.

## Mounting bearings with a tapered bore

Bearings with a tapered bore are mounted with an interference fit. To obtain the proper degree of interference, one of the following methods can be used:

### 1 Measuring the clearance reduction (table 7)

### 2 Measuring the lock nut tightening angle (table 7)

### 3 Measuring the axial drive-up (table 7)

### 4 Applying the SKF Drive-up Method

For bearings with  $d > 100$  mm, SKF recommends using the SKF Drive-up Method. This is a fast, reliable and safe method to achieve the appropriate interference fit. Additional information is available online at [skf.com/drive-up](http://skf.com/drive-up).

### 5 Measuring the inner ring expansion

Additional information is available online at [skf.com/sensormount](http://skf.com/sensormount).

For additional information about these mounting methods, refer to *Mounting bearings with a tapered bore*, page 203, or the *SKF bearing maintenance handbook*.

Applying the recommended values prevents the inner ring from creeping, but does not ensure correct radial internal clearance in operation. Additional influences from the bearing housing fit and temperature differences between the inner and outer rings must be considered carefully when selecting the bearing radial internal clearance class (Selecting initial internal clearance, [page 183](#)).

<sup>1)</sup> Not valid for the SKF Drive-up Method.

<sup>2)</sup> The listed values are valid only for solid steel shafts and general applications. They are to be used as guideline values only, as it is difficult to establish an exact starting position. Also, the axial drive-up, s, differs slightly between the different bearings series.

CARB toroidal roller bearings (fig. 1) have one row of long, slightly barrel-shaped symmetrical rollers and torus-shaped raceway profiles (fig. 2). They are non-locating bearings and accommodate exclusively radial loads. CARB bearings are often used to replace the non-locating spherical roller bearing in a locating/non-locating bearing arrangement.

## Bearing features

- **Accommodate misalignment**  
CARB bearings are self-aligning like spherical roller bearings or self-aligning ball bearings (fig. 3).
- **Accommodate axial displacement**  
CARB bearings compensate for thermal expansion of the shaft like cylindrical or needle roller bearings (fig. 4).

- **Wide assortment of dimension series**  
CARB bearings are available with the same boundary dimensions as corresponding spherical roller bearings, self-aligning ball bearings, cylindrical roller bearings and needle roller bearings (fig. 5).
- **Long service life**  
The special roller profile prevents stress peaks at the roller ends (fig. 6).
- **Low friction**  
Self-guiding rollers keep friction and frictional heat at low levels (fig. 7).
- **Improved wear resistance**  
All CARB bearings are upgraded SKF Explorer bearings (page 7).
- **Low noise**  
CARB bearings can reduce noise and vibration levels, for example, in paper machines and fans.

**Low friction and frictional heat****Long bearing system life**

CARB bearings provide benefits in self-aligning bearing arrangements (fig. 8). With a CARB bearing in the non-locating position, there are no internally induced axial forces, which results in multiple benefits:

- Less load extends the service life.
- The bearings run cooler, the lubricant lasts longer and maintenance intervals can be extended.
- Noise and vibration levels can be reduced.

# Designs and variants

## SKF standard assortment

The SKF standard assortment of CARB toroidal roller bearings matches the assortment of spherical roller bearings. It also includes bearings with a low cross-sectional height to meet requirements for minimum radial space. All CARB bearings are upgraded SKF Explorer bearings and are shown coloured blue in the product tables. The standard assortment includes:

- basic design bearings with cylindrical or tapered bore
  - taper 1:12 (designation suffix K)
  - taper 1:30 (designation suffix K30)
- sealed bearings

For sizes and variants not listed in the product tables, contact SKF.

## Basic design bearings

Depending on their series and size the following basic design CARB toroidal roller bearings are available as standard ([fig. 9](#)):

- bearings with a roller centred cage
- bearings with an inner ring centred cage
- full complement bearings with a retaining ring

The load carrying capacity of full complement CARB bearings is considerably higher than that of same-sized bearings with a cage.

### Sealed bearings

HNBR seals

NBR seals

## Sealed bearings

- are available, as standard, as small and medium-size full complement bearings with a cylindrical bore
- are typically used for low speeds and very heavy loads
- are suitable for both inner or outer ring rotation
- are fitted with a double-lip contact seal on one or both sides in a recess on the outer ring, sealing against the inner ring raceway
- are available with two different seal materials / designs ([fig. 10](#)):
  - sheet steel reinforced HNBR (designation suffix CS5)
  - sheet steel reinforced NBR (designation suffix NS) with enhanced sealing effectiveness – mainly intended for oscillating or very low speed applications

Bearings sealed on both sides are lubricated for the life of the bearing and are virtually maintenance-free. They are filled with one of the following greases ([table 1](#)):

- bearings with HNBR seals → SKF LGHB 2 grease as standard
- bearings with NBR seals → SKF LGEP 2 grease as standard
- other SKF greases on request

For additional information about greases, refer to *Selecting a suitable SKF grease*, [page 116](#).

## Cages

CARB bearings, if not a full complement of rollers, are fitted with one of the following cages:

- glass fibre reinforced PA46 cage, window-type, roller centred (designation suffix TN9)
- stamped steel cage, window-type, roller centred (no designation suffix)
- machined brass cage, window-type, roller centred (designation suffix M)
- machined brass cage, inner ring centred (designation suffix MB)

When used at high temperatures, some lubricants can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to *Cages*, [page 187](#).

## Customized bearings

SKF can customize bearings to meet the needs of applications where the bearings are subjected to unique operating conditions. For example, bearings for:

- paper mills or coaters in high precision execution
- very arduous operating conditions, e.g. continuous casters
- high temperature applications

For additional information about application-specific CARB bearings, contact the SKF application engineering service.

# Temperature limits

The permissible operating temperature for CARB bearings can be limited by:

- the dimensional stability of the bearing rings
- the cage
- the seals
- the lubricant

Where temperatures outside the permissible range are expected, contact SKF.

## Bearing rings

The rings of CARB bearings are heat stabilized up to 200 °C (390 °F).

## Cages

Steel or brass cages can be used at the same operating temperatures as the bearing rings. For temperature limits of polymer cages, refer to *Polymer cages*, [page 188](#).

## Seals

The permissible operating temperature for seals depends on the seal material:

- HNBR: -40 to +150 °C (-40 to +300 °F)
  - NBR: -40 to +90 °C (-40 to +195 °F)
- Temperatures up to 120 °C (250 °F) can be tolerated for brief periods.

Typically, temperature peaks are at the seal lip.

## Lubricants

Temperature limits for greases used in sealed CARB bearings are provided in [table 1, page 845](#). For temperature limits of other SKF greases, refer to *Selecting a suitable SKF grease*, [page 116](#).

When using lubricants not supplied by SKF, temperature limits should be evaluated according to the SKF traffic light concept ([page 117](#)).

# Permissible speed

The speed ratings in the [product table](#) indicate:

- the **reference speed**, which enables a quick assessment of the speed capabilities from a thermal frame of reference
- the **limiting speed**, which is a mechanical limit that should not be exceeded unless the bearing design and the application are adapted for higher speeds

For additional information, refer to *Operating temperature and speed*, [page 130](#).

# Design considerations

## Verification of axial displacement

The actual internal clearance can limit the possible axial displacement. Misalignment reduces the possible axial displacement. Therefore, the actual axial displacement should be verified.

### 1 Determine the required axial displacement

- Thermal expansion of the shaft can be estimated using  $s_{\text{req}} = \alpha L \Delta T$
- Where additional effects need to be considered, advanced simulation or tests may be required.

Fig. 11

### Permissible axial displacement

Diagram 1

The clearance window for a C 3052 CARB bearing with a maximum operating clearance of 0,150 mm

Fig. 12

## 2 Determine the maximum misalignment

- Estimate the misalignment  $\beta$  of the housing seats based on specified tolerances.
- Where additional effects need to be considered, advanced simulation or tests may be required.

## 3 Check the permissible axial displacement

Check the permissible axial displacement in both directions, depending on the bearing used (fig. 11):

- open bearing with a cage
- full complement bearing with a retaining ring
- sealed bearing

$$s_{\text{req}} < s_1 - \beta k_1 B$$

or

$$s_{\text{req}} < s_2 - \beta k_1 B$$

Where  $s_{\text{req}}$  is too large, consider *Offset mounting*, page 852.

## 4 Check the internal clearance

- Determine the clearance reduction caused by axial displacement.

$$C_{\text{red}} = \frac{k_2 s_{\text{req}}^2}{B}$$

- Determine the amount of clearance reduction from other effects and evaluate the residual clearance (*Selecting initial internal clearance*, page 183).

### Calculation example

Application (fig. 12)

- Bearing C 3040
  - $d = 200$  mm
  - $D = 310$  mm
  - $B = 82$  mm
  - Normal clearance: min.  $170 \mu\text{m}$
  - $s_1 = 15,2$  mm
  - $k_1 = 0,123$
  - $k_2 = 0,095$
- Shaft length  $L = 3\,000$  mm
- Temperature range for the shaft: 20 to  $90^{\circ}\text{C}$  (70 to  $195^{\circ}\text{F}$ )
- Max. misalignment:  $0,46^{\circ}$

Verification of axial displacement:

#### 1 Required axial displacement

$$s_{\text{req}} = \alpha L \Delta T$$

$$s_{\text{req}} = 12 \times 10^{-6} \times 3\,000 \times (90 - 20)$$

$$= 2,5 \text{ mm}$$

#### 2 Max. misalignment

Input provided:  $0,46^{\circ}$

#### 3 Checking the permissible axial displacement

$$s_{\text{req}} < s_1 - \beta k_1 B$$

$$2,5 < 15,2 - 0,46 \times 0,123 \times 82 \approx 10,5$$

→ okay

#### 4 Checking the internal clearance

$$C_{\text{red}} = \frac{k_2 s_{\text{req}}^2}{B}$$

$$C_{\text{red}} = \frac{0,095 \times 2,5^2}{82} \approx 0,007$$

Min. internal clearance when the bearing is displaced:

$$170 - 7 = 163 \mu\text{m}$$

Determine the clearance reduction caused by other effects (e.g. interference fit, temperature difference between inner and outer rings) and evaluate the residual clearance (*Selecting initial internal clearance*, page 183)

## Free space on both sides of the bearing

To enable axial displacement of the shaft relative to the housing, free space must be provided on both sides of the bearing as indicated in [fig. 13](#). The value for the width of this free space is based on:

- the value  $C_a$  ([product table, page 856](#))
- the expected axial displacement of the bearing rings from the central position during operation
- the displacement of the rings caused by misalignment

### Calculating the free space required on both sides of the bearing

$$C_{areq} = C_a + 0,5 (s + \beta k_1 B)$$

where

$B$  = bearing width [mm]

$C_a$  = minimum width of space required on both sides of the bearing [mm] ([product table](#))

$C_{areq}$  = width of space required on both sides of the bearing [mm]

$k_1$  = misalignment factor ([product table](#))

$s$  = relative axial displacement of rings, e.g. thermal shaft expansion [mm]

$\beta$  = misalignment [°]

## Offset mounting

Where considerable thermal changes in shaft length are a possibility, the inner ring can be mounted offset, relative to the outer ring, up to the axial displacement limit  $s_1$  or  $s_2$  ([fig. 11, page 850](#)) in the direction opposite to the expected axial displacement ([fig. 14](#)). The extended permissible axial displacement is used, for example, in the self-aligning bearing arrangements of drying cylinders in paper machines.

## Bearings on sleeves

CARB bearings with a tapered bore can be mounted with:

- an adapter sleeve on plain or stepped shafts ([fig. 15](#)):
  - Adapter sleeves are supplied complete with a locking device.
  - Use appropriate SKF adapter sleeve assemblies to prevent the locking device from interfering with the cage ([product table, page 868](#)).
- a withdrawal sleeve on stepped shafts ([fig. 16](#))

Check axial displacement carefully, as it could be that  $s_1$  ([product table, page 856](#)) cannot be fully realized.

For additional information about sleeves, refer to *Adapter sleeves*, [page 1065](#), and *Withdrawal sleeves*, [page 1087](#).

## Appropriate bearing housings

SKF standard bearing housings are available for most CARB bearings in the C 30, C 31, C 22 and C 23 series.

The two common arrangements when using standard housings are:

- CARB bearings with a tapered bore on an adapter sleeve and a plain shaft
- CARB bearings with a cylindrical bore on a stepped shaft

The comprehensive assortment of SKF bearing housings is provided online at [skf.com/housings](http://skf.com/housings).

# Mounting

During handling, the rings and roller complement of CARB toroidal roller bearings may be axially displaced from their normal position. This is especially likely where CARB bearings are mounted with the shaft or housing in the vertical position:

- 1 The roller complement, together with the inner or outer ring, will move downward and result in no more clearance.
- 2 When the bearing rings expand or contract as a result of an interference fit, preload is likely to result.

Therefore, wherever possible:

- Mount CARB bearings with the shaft or housing in the horizontal position.
- Rotate the inner or outer ring to align the rollers during mounting.

Where this is not feasible, use a bearing handling tool or other device to keep the bearing components arranged centrally.

# Mounting bearings with a tapered bore

Bearings with a tapered bore are mounted with an interference fit, by using one of the following methods:

- 1 **Measuring the clearance reduction** ([table 5, page 854](#))
- 2 **Measuring the lock nut tightening angle** ([table 5](#))
- 3 **Measuring the axial drive-up** ([table 5](#))
- 4 **Applying the SKF Drive-up Method**  
For bearings with  $d > 100$  mm, SKF recommends using the SKF Drive-up Method. This is a fast, reliable and safe method to achieve the appropriate interference fit. Additional information is available online at [skf.com/drive-up](http://skf.com/drive-up).
- 5 **Measuring the inner ring expansion**  
Additional information is available online at [skf.com/sensormount](http://skf.com/sensormount).

For additional information about these mounting methods, refer to *Mounting bearings with a tapered bore*, [page 203](#), or the *SKF bearing maintenance handbook*.

Applying the recommended values prevents the inner ring from creeping, but does not ensure correct radial internal clearance in operation. Additional influences from the bearing housing fit and temperature differences between the inner and outer rings must be considered carefully when selecting the bearing radial internal clearance class (*Selecting initial internal clearance*, [page 183](#)).

<sup>1)</sup> Not valid for the SKF Drive-up Method.

<sup>2)</sup> The listed values are valid only for solid steel shafts and general applications. They are to be used as guideline values only, as it is difficult to establish an exact starting position. Also, the axial drive-up, *s*, differs slightly between the different bearings series.

SKF cylindrical roller thrust bearings ([fig. 1](#)) are designed to accommodate heavy axial loads and impact loads. They must not be subjected to any radial load. The bearings are very stiff and require little axial space.

## Bearing features

- **Separable design**

Shaft washer, housing washer, cylindrical roller and cage thrust assembly can be mounted separately.

- **Extended bearing service life**

To prevent stress peaks, the roller ends are relieved slightly to modify the line contact between the raceway and rollers.

# Designs and variants

SKF supplies cylindrical roller thrust bearings in different series ([fig. 2](#)):

- 811 and 812 series bearings with one row of rollers  
They are mainly used in applications where thrust ball bearings do not have sufficient load carrying capacity.
- 893 and 894 series bearings with two rows of rollers

## Single direction bearings

As standard, cylindrical roller thrust bearings are available as single direction bearings ([fig. 2](#)) and can accommodate axial loads in one direction only.

## Double direction bearings

- can accommodate axial loads in both directions
- can be created by combining two cylindrical roller and cage thrust assemblies and two bearing washers with an intermediate washer

Depending on the design, an intermediate washer can be shaft or housing centred ([fig. 3](#)).

Intermediate washers must have the same surface finish and hardness as bearing washers. SKF does not supply intermediate washers, but provides material specifications and dimensional data on request.

For additional information, refer to *Design considerations*, [page 885](#).

### Cylindrical roller and cage thrust assemblies

- are identified by the prefix K ([fig. 4](#))
- can accommodate axial loads in one direction only
- can be combined with washers in the WS, GS and LS series ([Bearing washers](#))
- can be used without washers in applications where:
  - adjacent components can serve as raceways
  - bearing arrangements with a low axial section height are required

### Bearing washers

SKF can also supply the components of cylindrical roller thrust bearings also separately. Additional to cylindrical roller and cage thrust assemblies the included bearing washers ([fig. 5](#)) are listed in the [product table, page 888](#).

#### Shaft washers

- are identified by the prefix WS
- are made of hardened carbon chromium bearing steel
- have a precision-ground raceway surface
- have a ground bore

#### Housing washers

- are identified by the prefix GS
- are made of hardened carbon chromium bearing steel
- have a precision-ground raceway surface
- have a ground outside surface

SKF recommends using both of these washers in high-speed applications where accurate centring of the bearing washers is required.

#### LS series universal washers

- can be used as both shaft or housing washers for bearings in the 811 series
- are used for applications where accurate centring of the bearing washers is not necessary
- are used where low speeds are involved

For additional information about LS series washers, refer to *Needle roller thrust bearings*, [page 895](#).

# Cages

SKF cylindrical roller thrust bearings are fitted with one of the cages shown in [table 1](#).

When used at high temperatures, some lubricants can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to *Cages*, [page 187](#).

## Temperature limits

The permissible operating temperature for cylindrical roller thrust bearings can be limited by:

- the dimensional stability of the bearing washers and rollers
- the cage
- the lubricant

Where temperatures outside the permissible range are expected, contact SKF.

### Bearing washers and rollers

The bearings are heat stabilized up to at least 120 °C (250 °F).

### Cages

Brass cages can be used at the same operating temperatures as the bearing washers and rollers. For temperature limits of polymer cages, refer to *Polymer cages*, [page 188](#).

### Lubricants

For temperature limits of SKF greases, refer to *Selecting a suitable SKF grease*, [page 116](#).

When using lubricants not supplied by SKF, temperature limits should be evaluated according to the SKF traffic light concept, [page 117](#).

## Permissible speed

The speed ratings in the [product table](#), [page 888](#) indicate:

- the **reference speed**, which enables a quick assessment of the speed capabilities from a thermal frame of reference
- the **limiting speed**, which is a mechanical limit that should not be exceeded unless the bearing design and the application are adapted for higher speeds

For additional information, refer to *Operating temperature and speed*, [page 130](#).

# Design considerations

## Abutment dimensions

Abutment dimensions should fulfil the following:

- Support surfaces in housings and on shafts should be at right angles to the shaft axis and provide uninterrupted support over the entire washer face.
- The abutment diameter on the shaft should be  $\geq d_{a \min}$  and in the housing  $\leq D_{a \max}$  (**fig. 6**). Values for  $d_{a \min}$  and  $D_{a \max}$  are listed in the **product table, page 888**
- Shafts and housings should be manufactured to suitable tolerance classes (**table 4**) to provide satisfactory radial guidance for the individual thrust bearing components.
  - Housing centred washers require a radial gap between the shaft and washer bore.
  - Shaft centred washers require a radial gap between the washer and the housing bore.

Cylindrical roller and cage thrust assemblies are generally centred radially by the shaft to reduce the circumferential speed at which the cage slides against the guiding surface. This is particularly important for higher-speed applications. The guiding surface should be ground.

## Raceways on shafts and in housings

- should have the same hardness, surface finish and axial run-out as a bearing washer, if the load carrying capacity of a cylindrical roller and cage thrust assembly is to be fully exploited
- should be designed using the dimensions  $E_a$  and  $E_b$  (**product table, page 888**), which take radial displacement of the roller set into consideration

For additional information, refer to **Raceways on shafts and in housings, page 179**.

SKF needle roller thrust bearings are fitted with a form-stable cage to reliably retain and guide a large number of needle rollers.

Needle roller thrust bearings provide a high degree of stiffness within a minimum axial space. In applications where the faces of adjacent machine components can serve as raceways, needle roller thrust bearings take up no more space than a conventional thrust washer.

## Bearing features

- **Accommodate heavy axial loads and peak loads**

The very small diameter deviation of the rollers within one assembly enables these bearings to accommodate heavy axial loads and peak loads.

- **Extended bearing service life**

To prevent stress peaks, the roller ends are relieved slightly to modify the line contact between the raceway and rollers.

## Designs and variants

SKF supplies needle roller thrust bearings in two designs:

- needle roller and cage thrust assemblies, AXK series ([fig. 1](#))
- needle roller thrust bearings with a centring flange, AXW series ([fig. 2](#))

In applications where adjacent components cannot serve as raceways, the assemblies can be combined with bearing washers in different series ([Bearing washers, page 898](#)).

Fig. 2

## Needle roller and cage thrust assemblies

AXK series needle roller and cage thrust assemblies (fig. 1):

- are available for  $4 \leq d \leq 160$  mm
- can accommodate axial loads in one direction only
- can be combined with washers in the LS, AS, GS 811 or WS 811 series (Bearing washers, page 898) in applications where adjacent components cannot serve as raceways

## Double direction bearings

Double direction bearings:

- can accommodate axial loads in both directions
  - can be created by combining two needle roller and cage thrust assemblies and two bearing washers with an intermediate washer
- Depending on the design, an intermediate washer can be shaft or housing centred (fig. 3 and fig. 4).

Intermediate washers must have the same hardness and surface finish as bearing washers. SKF does not supply intermediate washers, but provides material specifications and dimensional data on request.

For additional information, refer to Design considerations, page 903.

## Needle roller thrust bearings with a centring flange

AXW series needle roller thrust bearings with a centring flange (fig. 2 and fig. 5):

- are available for  $10 \leq d \leq 50$  mm
- accommodate axial loads in one direction only
- consist of a needle roller and cage thrust assembly and a thrust washer with a centring flange

The flange facilitates mounting and accurately centres the housing washer radially (fig. 6 and fig. 7).

## Combined needle roller bearing arrangements

To accommodate combined radial and axial loads, needle roller thrust bearings in the AXW series can be combined with the following radial needle roller bearings:

- drawn cup needle roller bearings with a closed end or with open ends (fig. 6)
- needle roller bearings with machined rings (fig. 7)

These arrangements provide a cost-effective and compact solution for combined loads.

## Bearing washers

Bearing washers are required in applications where adjacent machine components cannot serve as raceways.

Appropriate washers are listed in the [product tables](#), [page 906](#) and must be ordered separately, because of the number of possible combinations.

The following series can be combined with needle roller thrust bearings:

### LS series universal washers

([fig. 8](#))

- are made of hardened carbon chromium bearing steel
- can be used as shaft or housing washers for needle roller thrust bearings in the AXK series
- can be used as shaft washers for bearings in the AXW series
- are available for  $6 \leq d \leq 160$  mm
- raceway surface is ground, while all other surfaces are turned
- are used for applications where accurate centring of the washers is not necessary or where low speeds are involved
- washer face opposite the side with the chamfers is the raceway surface and should face the rollers

### AS series thin universal washers

([fig. 9](#))

- are 1 mm thick
- are made of spring steel and hardened
- can be used as shaft or housing washers for needle roller thrust bearings in the AXK series
- can be used as shaft washers for bearings in the AXW series
- are available for  $4 \leq d \leq 160$  mm
- can be used to provide a cost-effective bearing solution, if adjacent machine components are not hardened, but have adequate stiffness and the requirements to geometrical tolerances are moderate

Both faces of the washers are polished and can be used as raceways.

## 811 series shaft (prefix WS) and housing washers (prefix GS)

- are used primarily with cylindrical roller and cage thrust assemblies
- can also be combined with needle roller and cage thrust assemblies
- can be used in high-speed applications where accurate centring of the bearing washers is required

For additional information about 811 series washers, refer to [Cylindrical roller thrust bearings](#), [page 877](#).

## Cages

SKF needle roller thrust bearings are fitted with one of the cages shown in [table 1](#). Bearings in the AXW series are fitted exclusively with steel cages.

When used at high temperatures, some lubricants can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to [Cages](#), [page 187](#).

## Temperature limits

The permissible operating temperature for needle roller thrust bearings can be limited by:

- the dimensional stability of the bearing washers and rollers
- the cage
- the lubricant

Where temperatures outside the permissible range are expected, contact SKF.

### Bearing washers and rollers

The bearings are heat stabilized up to at least 120 °C (250 °F).

### Cages

Steel cages can be used at the same operating temperatures as the bearing washers and rollers. For temperature limits of polymer cages, refer to *Polymer cages*, [page 188](#).

### Lubricants

For temperature limits of SKF greases, refer to *Selecting a suitable SKF grease*, [page 116](#).

When using lubricants not supplied by SKF, temperature limits should be evaluated according to the SKF traffic light concept ([page 117](#)).

## Permissible speed

The speed ratings in the [product tables, page 906](#) indicate:

- the **reference speed**, which enables a quick assessment of the speed capabilities from a thermal frame of reference
- the **limiting speed**, which is a mechanical limit that should not be exceeded unless the bearing design and the application are adapted for higher speeds

For additional information, refer to *Operating temperature and speed*, [page 130](#).

# Design considerations

## Abutment dimensions

Abutment dimensions should fulfil the following:

- Support surfaces on shafts and in housings should be at right angles to the shaft or housing axis and should provide uninterrupted support over the entire washer face.
- The abutment diameter on the shaft should be  $\leq E_a$  and in the housing  $\geq E_b$ .  
Values for  $E_a$  and  $E_b$  (product tables, page 906) take the movement and position of the roller set into consideration.
- Shafts and housings should be manufactured to suitable tolerance classes (table 4) to provide satisfactory radial guidance for the individual thrust bearing components:
  - Housing centred washers → radial space between the shaft and washer bore required
  - Shaft centred washers → radial space between the washer and the housing bore required

Needle roller and cage thrust assemblies in the AXW series are generally combined with drawn cup needle roller bearings (fig. 6, page 897) or needle roller bearings with machined rings (fig. 7, page 897). The same housing tolerance must be selected for the centring flange as for the radial bearing.

Needle roller and cage thrust assemblies are generally shaft centred, to reduce the circumferential speed at which the cage slides against the guiding surface. This is particularly important for higher-speed applications. The guiding surface should be ground.

## Raceways on shafts and in housings

- should have the same hardness, surface finish and axial run-out as a bearing washer, if the load carrying capacity of a needle roller and cage thrust assembly is to be fully exploited
- should be designed using the dimensions  $E_a$  and  $E_b$  (product tables, page 906), which take radial displacement of the roller set into consideration

For additional information, refer to **Raceways on shafts and in housings**, page 179.

SKF spherical roller thrust bearings have specially designed raceways and asymmetrical rollers. The bearings can accommodate axial loads acting in one direction and simultaneously acting radial loads. The load is transmitted between the raceways via the rollers at an angle to the bearing axis, while the flange guides the rollers (**fig. 1**).

## Bearing features

### • High load carrying capacity

The large number of rollers, which have an optimum conformity with the washer raceways, enables the bearings to accommodate heavy axial and simultaneously acting radial loads.

### • Accommodate misalignment

SKF spherical roller thrust bearings are self-aligning and can accommodate misalignment (**fig. 2**).

### • Separable design

SKF spherical roller thrust bearings are separable, making it possible to mount and dismount the housing washer separately from the shaft washer and roller and cage assembly. In addition this facilitates maintenance inspections.

### • High speed capability

The cage designs and the optimum conformity of the rollers with the washer raceways make the bearings suitable for relatively high speeds.

### • Long service life

The special roller profile reduces edge stresses at the roller/raceway contact.

### • Low friction

The optimized roller end / flange contact keeps frictional heat at low level, even at high speeds.

# Designs and variants

## Basic design bearings

Depending on their series and size, SKF spherical roller thrust bearings are manufactured to two basic designs ([fig. 3](#)). Their cage forms a non-separable unit with the shaft washer and rollers.

### Bearings with no designation suffix (e.g. 29272)

- are fitted with a machined brass prong-type cage as standard

### E design bearings (designation suffix E)

- have larger rollers and an optimized internal design for increased load carrying capacity
- are fitted with one of the following cages, depending on bearing size:
  - size  $\leq 68$  → stamped steel window-type cage
  - size  $\geq 72$  → machined metal prong-type cage

## SKF Explorer bearings

For information, refer to [page 7](#).

## Cages

Cages in SKF spherical roller thrust bearings are an integral part of the bearing internal design. All SKF spherical roller thrust bearings contain a strong metal cage. This enables them to tolerate high temperatures and operate with all lubricants.

For additional information about the suitability of cages, refer to [Cages](#), [page 187](#).

# Temperature limits

The permissible operating temperature for spherical roller thrust bearings can be limited by:

- the dimensional stability of the bearing washers
- the lubricant

Where temperatures outside the permissible range are expected, contact SKF.

## Bearing washers

The washers of SKF spherical roller thrust bearings are heat stabilized up to 200 °C (390 °F).

## Lubricants

For temperature limits of SKF greases, refer to *Selecting a suitable SKF grease*, [page 116](#).

When using lubricants not supplied by SKF, temperature limits should be evaluated according to the SKF traffic light concept ([page 117](#)).

# Permissible speed

The speed ratings in the [product table](#), [page 922](#), indicate:

- the **reference speed**, which enables a quick assessment of the speed capabilities from a thermal frame of reference
- the **limiting speed**, which is a mechanical limit that should not be exceeded unless the bearing design and the application are adapted for higher speeds

For additional information, refer to *Operating temperature and speed*, [page 130](#).

# Design considerations

## Abutment dimensions

The abutment dimensions  $d_{a\min}$  and  $D_{a\max}$  listed in the [product table](#), [page 922](#), apply for axial bearing loads  $F_a \leq 0,1 C_0$ .

For heavier bearing loads, it may be necessary to support the shaft and housing washers over their entire side faces ( $d_a = d_1$  and  $D_a = D_1$ ).

For heavy loads, where  $P > 0,1 C_0$ , the shaft washer bore must be fully supported by the shaft, preferably by an interference fit. Even the housing washer should be radially supported ([fig. 4](#)).

For additional information about dimensioning washer supports, contact the SKF application engineering service.

## Recessed housing bore for bearings with a stamped steel cage

For bearings fitted with a stamped steel window-type cage, the housing bore must be recessed ([fig. 5](#)) to prevent the cage from

contacting the housing during possible misalignment. SKF recommends the following guideline values for the recess diameter:

- $D + 15$  mm for bearings with an outside diameter  $D \leq 380$  mm
- $D + 20$  mm for bearings with an outside diameter  $D > 380$  mm

## Axial clearance in bearing arrangements

SKF spherical roller thrust bearings in face-to-face or back-to-back arrangements should be preloaded. However, at the relatively low speeds shown within the green area in [diagram 1](#), the application can be designed to operate with a small axial clearance. For these applications, bearings with a modified shaft washer (designation suffix VU029) should be used. Small axial clearance enables simple and cost-effective bearing arrangements to be used, e.g. for horizontal shaft applications at relatively low speeds, as no external preload is necessary.

For additional information about bearing arrangements with axial clearance, contact the SKF application engineering service.

# Lubrication

Generally, SKF spherical roller thrust bearings can be lubricated with oil or grease containing EP additives.

Where lubricating with grease, the roller end / flange contacts must be supplied with an adequate amount of grease. Make sure to use a grease with high oil bleeding, such as SKF LGWM 1, LGWM 2 or LGEP 2 (*Selecting a suitable SKF grease*, [page 116](#)).

## Pumping effect in oil lubricated applications

The internal design of spherical roller thrust bearings creates a pumping action, which produces a flow from the small to the large roller end face, that can be taken advantage of in oil lubricated applications. This pumping action occurs in applications where the shaft is vertical or horizontal ([fig. 6](#)) and should be considered when selecting the type of lubricant and sealing arrangement.

For bearings with a machined cage used in high-speed applications, SKF recommends the oil injection lubrication method ([fig. 7](#)).

For additional information about lubricating spherical roller thrust bearings, contact the SKF application engineering service.

# Mounting

SKF spherical roller thrust bearings are separable, making it possible to mount and dismount the housing washer separately from the shaft washer and roller and cage assembly.

Where a spherical roller thrust bearing with a machined metal cage is to be replaced by an E design bearing with a stamped steel window-type cage, and axial forces are transmitted via the cage guiding sleeve, a spacer ring must be inserted between the shaft abutment and the shaft washer ([fig. 8](#)).

The spacer ring must be hardened and its side faces should be ground. Appropriate spacer ring dimensions for SKF spherical roller thrust bearings are listed in the [product table, page 922](#).

SKF cam rollers (yoke-type track rollers based on ball bearings) are designed to run on all types of tracks and to be used in cam drives, conveyor systems, etc.

The outer ring running surface is crowned as standard. Double row cam rollers are also available with a cylindrical (flat) outer ring running surface.

SKF supplies cam rollers greased, sealed and ready-to-mount. They are available in two main designs and also as variants of these:

- single row cam rollers based on deep groove ball bearings in the 62 series ([fig. 1](#))
- double row cam rollers based on double row angular contact ball bearings in the 32 dimension series ([fig. 2](#))

## Cam roller features

- **Accommodate high radial loads**  
The thick-walled outer ring enables high radial loads, while reducing distortion and bending stresses.
- **Accommodate tilting moments**  
Double row cam rollers accommodate higher tilting moments than single row cam rollers.
- **Long service life**  
The crowned outer ring running surface is beneficial for applications where outer ring tilting relative to the track may occur or where edge stresses need to be minimized.
- **Relatively high speed capability**

## Designs and variants

### Single row cam rollers

- are based on deep groove ball bearings in the 62 series ([fig. 1](#))
- have a thick-walled outer ring with its running surface crowned
- are capped with a sheet steel reinforced NBR contact seal on both sides
- are greased for the life of the bearing and cannot be relubricated ([table 1](#))

When capped bearings must operate under certain conditions, such as very high speeds or high temperatures, some grease may leak. For bearing arrangements where this would be detrimental, appropriate actions should be taken.

### Double row cam rollers

- are based on double row angular contact ball bearings in the 32 dimension series ([fig. 2](#))
  - have a thick-walled outer ring with its running surface available in two designs:
    - crowned as standard (series designation 3058.. C)
    - cylindrical (flat) (series designation 3057.. C)
  - have a 30° contact angle, enabling, together with the two ball sets, tilting moments to be accommodated
  - are supplied capped in two variants:
    - with a sheet steel shield on both sides that extends into a recess on the inner ring (designation suffix -2Z)
    - with an NBR contact seal on both sides (designation suffix -2RS1)
- These cam rollers are not listed in this catalogue, but can be found online at [skf.com/go/17000-14-2](http://skf.com/go/17000-14-2).
- are greased for the life of the bearing under normal operating conditions ([table 1](#))

- should be relubricated, if:
  - subjected to moisture or solid contaminants
  - they run for long periods at temperatures above 70 °C (160 °F)
- have a lubrication hole in the inner ring
  - Where suitable ducts are provided in the pin, the bearings are easy to relubricate.
  - The grease should be applied slowly to avoid damaging the shields or seals.

When capped bearings must operate under certain conditions, such as very high speeds or high temperatures, grease may appear between the inner ring and capping device. For bearing arrangements where this would be detrimental, appropriate actions should be taken.

## Cages

SKF cam rollers are fitted with one of the cages shown in [table 2](#). Double row cam rollers are equipped with two cages.

When used at high temperatures, some lubricants can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to [Cages](#), [page 187](#).

## Temperature limits

The permissible operating temperature for cam rollers can be limited by:

- the dimensional stability of the bearing rings and balls
- the cage
- the seals
- the lubricant

Where temperatures outside the permissible range are expected, contact SKF.

### Bearing rings and balls

SKF cam rollers are heat stabilized up to at least:

- 120 °C (250 °F) for single row cam rollers
- 150 °C (300 °F) for double row cam rollers

### Cages

Steel cages can be used at the same operating temperatures as the bearing rings and balls. For temperature limits of PA66 cages, refer to *Polymer cages*, [page 188](#).

### Seals

The permissible operating temperature for NBR seals is -40 to +100 °C (-40 to +210 °F). Temperatures up to 120 °C (250 °F) can be tolerated for brief periods.

Typically, temperature peaks are at the seal lip.

### Lubricants

Temperature limits for greases used in SKF cam rollers are provided in [table 1](#), [page 933](#). For temperature limits of other SKF greases, refer to *Selecting a suitable SKF grease*, [page 116](#).

When using lubricants not supplied by SKF, temperature limits should be evaluated according to the SKF traffic light concept ([page 117](#)).

## Speed limits

The limiting speed listed in the [product tables](#) is a mechanical limit that should not be exceeded unless the bearing design and the application are adapted for higher speeds.

For additional information, refer to *Operating temperature and speed*, [page 130](#).

## Design considerations

### Pins

Pins or shafts should be machined to tolerance class g6(ⓔ):

- for normal operating conditions, such as stationary inner ring load
- where easy displacement of the inner ring is required

## Support surfaces

Continuously axial loaded cam rollers should be supported over the entire inner ring side face ([fig. 3](#)) and the support surface should be dimensioned according to diameter  $d_1$  ([product tables](#), [page 938](#)).

## Guide flanges

For rails or cams with guide flanges, the recommended flange height  $h_a$  ([fig. 3](#)) should be:

$$h_a \leq 0,5 (D - D_1)$$

The values for the outer ring diameters  $D$  and  $D_1$  are listed in the product tables.

SKF support rollers (yoke-type track rollers based on roller bearings) are designed to run on all types of tracks and to be used in cam drives, conveyor systems, etc.

SKF support rollers are based on needle or cylindrical roller bearings.

SKF supplies them ready-to-mount. To meet the requirements of different applications, they are available in several designs and variants ([fig. 1](#)):

- with or without a cage
- with or without flange rings
- with or without an inner ring
- with or without seals (sealed or open)
- with the outer ring running surface profile:
  - crowned as standard
  - cylindrical (flat)

## Support roller features

### • Accommodate high radial loads

The thick-walled outer ring enables high radial loads, while reducing distortion and bending stresses.

### • Long service life

The crowned outer ring running surface is beneficial for applications where outer ring tilting relative to the track may occur or where edge stresses need to be minimized.

# Designs and variants

SKF support rollers are available without or with flange rings (fig. 2). They have a thick-walled outer ring with its running surface crowned as standard. However, support rollers with a cylindrical (flat) running surface are also available (designation suffix X).

Support rollers without flange rings require adjacent components to guide the outer ring and cage axially.

Support rollers with flange rings do not need adjacent components to guide the outer ring and cage axially (fig. 3). Axial loads, which are induced when shafts are not horizontal or aligned properly, are accommodated by the flange rings.

## Support rollers without flange rings

- require adjacent components to guide the outer ring and cage axially
- are based on needle roller bearings
- are available:
  - with an inner ring, which is slightly wider than the outer ring to avoid axial clamping of the outer ring
  - without an inner ring (designation prefix R), intended for arrangements where the pin or shaft is hardened and ground

These support rollers are not listed in this catalogue, but can be found online at [skf.com/go/17000-15-3](http://skf.com/go/17000-15-3).

## (R)STO design support rollers

- are available (fig. 4):
  - with an inner ring that can be mounted separately from the outer ring and roller and cage assembly, which must always be kept together as supplied
  - without an inner ring (prefix R)
  - only open (without seals)

## (R)NA 22...2RS design support rollers

- are available (fig. 5):
  - with an inner ring that can be mounted separately from the outer ring and roller and cage assembly
  - without an inner ring (prefix R)
  - greased and capped with a sheet steel reinforced NBR contact seal on both sides
- have the needle roller and cage assembly axially guided between two integral flanges in the outer ring to form a non-separable unit

## Support rollers with flange rings

- do not need adjacent components to guide the outer ring and cage axially (fig. 3, page 945)
- are non-separable units
- have different flange designs:
  - pressed-on flange rings (NATR and NATV designs)
  - loose flange rings (NUTR, PWTR and NNTR designs)
- accommodate axial loads that can occur because of skew or tilting

### NATR and NATV design support rollers

- are based on (fig. 6):
  - a needle roller and cage assembly (NATR design)
  - a full complement of needle rollers (NATV design)
- have the outer ring axially guided by pressed-on flange rings, forming a gap-type seal

- are also available with an axial sliding ring on both sides (designation suffixes PPA, fig. 7, and PPXA):
  - made of PA66
  - forming narrow labyrinth seals with the outer ring in a radial direction, to protect against coarse contaminants
  - serving as contact seals in an axial direction to retain grease reliably in the bearing
  - improving lubrication conditions in the bearing, keeping friction and frictional heat low, and extending grease life

### NUTR .. A design support rollers

- are based on double row full complement cylindrical roller bearings without an integral flange between the two roller sets (fig. 8)
- have an outer ring with two integral flanges, which guide the roller sets axially
- have an inner ring with two loose flange rings, which guide the outer ring axially via the roller sets
- have a sheet metal angle ring pressed into the outer ring shoulder on both sides:
  - forming an effective labyrinth seal
  - extending over the flange rings, making the bearing non-separable
- accommodate relatively heavy axial loads that can occur because of skew or tilting
- can be supplied with a reinforced (thicker) outer ring to accommodate heavy peak loads (e.g. NUTR 50 A → NUTR 50110 A)

### PWTR ...2RS design support rollers

- are based on double row full complement cylindrical roller bearings (fig. 9)
- have an outer ring with three integral flanges, which guide the roller sets axially
- have an inner ring with two loose flange rings, which guide the outer ring axially via the roller sets
- have a relatively large grease quantity between the two roller sets
- are fitted on both sides with an NBR contact seal, being integral with a sheet metal angle ring that is pressed into the outer ring shoulder:
  - to press against the flange rings
  - extending over the flange rings, making the bearing non-separable
- accommodate relatively heavy axial loads that can occur because of skew or tilting
- can be supplied with a reinforced (thicker) outer ring to accommodate heavy peak loads (e.g. PWTR 50.2RS → PWTR 50110.2RS)

# NNTR ...2ZL design support rollers

- are based on double row full complement cylindrical roller bearings (fig. 10)
- have an outer ring with three integral flanges, which guide the roller sets axially
- have an inner ring with two loose flange rings, which guide the outer ring axially via the roller sets
- have a relatively large grease quantity between the two roller sets
- are fitted with a lamellar seal on both sides, inserted into recesses in the shoulders of the flange rings and the outer ring, making the bearing non-separable
- accommodate very heavy radial loads and relatively heavy axial loads that can occur because of skew or tilting

## Cages

SKF support rollers, if not a full complement of rollers, are fitted with one of the cages shown in table 1. The standard cage is not identified in the bearing designation.

When used at high temperatures, some lubricants can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to *Cages*, page 187.

# Lubrication

SKF support rollers are supplied greased (table 1, page 933).

(R)STO design support rollers can be oil or grease lubricated. In applications where oil is used, SKF recommends thoroughly washing the initial grease fill from the bearing prior to operation.

For general information, refer to *Lubrication*, page 109.

## Relubrication requirements

Support rollers:

- should be relubricated regularly to achieve their full service life, even if the initial grease fill still has its full lubricating properties
- used in applications where there are light loads, relatively low speeds and clean surroundings can operate for long periods before relubrication is required

- that operate under contaminated and damp conditions at high speeds or at temperatures > 70 °C (160 °F) require more frequent relubrication
- without a cage (full complement of rollers) require more frequent relubrication

## Relubrication features

The inner rings of SKF support rollers have one lubrication hole, except:

- NNTR designs with  $d \leq 90$  mm → three lubrication holes
- NNTR designs with  $d \geq 100$  mm → six lubrication holes

If suitable ducts are provided in the pin, the bearings are easy to relubricate.

# Temperature limits

The permissible operating temperature for support rollers can be limited by:

- the dimensional stability of the bearing rings and rollers
- the cage
- the seals
- the lubricant

Where temperatures outside the permissible range are expected, contact SKF.

## Bearing rings and rollers

SKF support rollers are heat stabilized up to at least 140 °C (280 °F).

## Cages

Steel cages can be used at the same operating temperatures as the bearing rings and rollers. For temperature limits of PA66 cages, refer to *Polymer cages*, [page 188](#).

## Seals

The permissible operating temperature for seals depends on the seal material:

- NBR: –40 to +100 °C (–40 to +210 °F)  
Temperatures up to 120 °C (250 °F) can be tolerated for brief periods.
- PA66 sliding rings: –30 to +100 °C (–20 to +210 °F)

Typically, temperature peaks are at the seal lip.

## Lubricants

Temperature limits for greases used in SKF support rollers are provided in [table 1](#), [page 947](#). For temperature limits of other SKF greases, refer to *Selecting a suitable SKF grease*, [page 116](#).

When using lubricants not supplied by SKF, temperature limits should be evaluated according to the SKF traffic light concept ([page 117](#)).

# Speed limits

The limiting speed listed in the [product tables](#) is a mechanical limit that should not be exceeded unless the bearing design and the application are adapted for higher speeds.

For additional information, refer to *Operating temperature and speed*, [page 130](#).

# Design considerations

## Pins

For general information, refer to *Bearing interfaces*, [page 139](#).

For support rollers with an inner ring, the pin/shaft should be machined to tolerance class g6<sup>Ⓔ</sup> under the following conditions:

- stationary inner ring load
- where easy displacement of the inner ring is required

To exploit the full load carrying capacity of support rollers without an inner ring, the pin/shaft should:

- be machined to tolerance class k5<sup>Ⓔ</sup>
- be machined to a surface finish similar to a bearing raceway
- have the same hardness as a bearing raceway

For additional information about raceways on shafts, refer to *Raceways on shafts and in housings*, [page 179](#).

## Axial gap

The following support rollers must be located without any axial gap:

- support rollers without flange rings, with an inner ring ([fig. 11](#))
- support rollers with flange rings ([fig. 12](#))

Support rollers without an inner ring must have an axial gap  $\geq 0,2$  mm between the outer ring and the support surfaces ([fig. 13](#)).

## Support surfaces

For support rollers without flange rings, the outer ring support surfaces:

- guide the outer ring and cage during operation
- must be fine turned
- must be free of burrs and clean
- should extend to at least half the outer ring side face ([fig. 11](#)), if unhardened – hardened surfaces may be smaller

Heavily loaded support rollers with flange rings should be axially supported:

- over the entire flange ring side faces ([fig. 12](#))
- according to diameter  $d_1$  ([product table](#), [page 956](#))

## Mounting

SKF recommends positioning the lubrication hole in the unloaded zone of the inner ring. Positioning is not needed for PWTR and NNTR design support rollers, which have the lubrication holes in the empty space between the two roller sets.

Where mounting the outer ring assembly and inner ring separately, care must be taken not to damage the seal lips.

SKF cam followers (stud-type track rollers) are designed to run on all types of tracks and to be used in cam drives, conveyor systems, etc.

SKF cam followers are based on either needle or cylindrical roller bearings. Instead of an inner ring, they have a threaded solid stud (pin).

SKF supplies them ready-to-mount. To meet the requirements of different applications, they are available in several designs and variants ([fig. 1](#)):

- with or without a cage
- with different stud designs:
  - a concentric seat
  - an eccentric collar
- with several sealing solutions
- with the outer ring running surface profile:
  - crowned as standard
  - cylindrical (flat)

In contrast to ball and roller bearings, where the bearing size refers to the bore diameter  $d$ , for cam followers the size refers to their outside diameter  $D$ .

Fig. 1

### Cam followers

- based on needle roller bearings
- with a cage
- with an eccentric collar

- based on cylindrical roller bearings
- without a cage
- with an eccentric collar

## Cam follower features

- **Accommodate high radial loads**

The thick-walled outer ring enables high radial loads, while reducing distortion and bending stresses.

- **Accommodate axial loads**

The flange rings enable cam followers to accommodate axial loads that can occur because of skew or tilting.

- **Long service life**

The crowned outer ring running surface is beneficial for applications where outer ring tilting relative to the track may occur or where edge stresses need to be minimized.

- **Easy to mount**

The threaded solid stud (pin) of cam followers can be quickly and easily attached to appropriate machine components by means of a hexagonal nut.

## Designs and variants

SKF cam followers have a thick-walled outer ring with its running surface crowned as standard. However, cam followers with a cylindrical (flat) running surface are also available (designation suffix X).

SKF cam followers are available in three basic designs ([fig. 2](#)):

- KR design
- NUKR design
- PWKR design

All three designs have the same main dimensions. They are available in different stud designs ([fig. 3](#)):

- a concentric seat
- an eccentric collar (E at the end of the basic designation) on the stud

The eccentric collar has a shrink-fit onto the stud, enabling less stringent positioning tolerances to be specified for associated components. The values of the adjustable eccentricity are listed in the [product table](#), [page 978](#).

## KR design cam followers

- are available based on:
  - a needle roller and cage assembly (fig. 4)
  - a full complement needle roller set (fig. 5, V in the basic designation)
 Cam followers based on a full complement of needle rollers accommodate higher loads than same-sized cam followers with a cage.
- have the outer ring axially guided by the pressed-on flange ring and the stud head (integral flange), forming a gap-type seal
- are also available with an axial sliding ring on both sides (designation suffixes PPA, fig. 6, or PPSKA, fig. 7, or PPXA):
  - made of PA66
  - forming narrow labyrinth seals with the outer ring in a radial direction, to protect against coarse contaminants
  - serving as contact seals in an axial direction to retain grease reliably in the bearing
  - improving lubrication conditions in the cam follower, keeping friction and frictional heat low, and extending grease life

### KR design cam followers, sizes 16 and 19

- without a designation suffix or with the designation suffix PPA (fig. 6)
  - have one slot in the head of the stud that enables the stud to be held in place by a screwdriver during mounting
  - have a relubrication hole for a press-in grease fitting or a plug if relubrication is not required in the centre of the slot (Accessories, page 968)
- with the designation suffix PPSKA (fig. 7)
  - have a hexagonal recess in the head of the stud that enables the stud to be held in place by a hexagonal key (Allen wrench) during mounting
  - have no relubrication features

### KR design cam followers, designation suffix B, sizes $\geq 22$

- have a hexagonal recess at each end of the stud (fig. 4), enabling the cam follower to be held in place by a hexagonal key (Allen wrench) during mounting
- have a relubrication hole for a press-in grease fitting in the centre of each hexagonal recess
- can accommodate adapters from a centralized lubrication system for sizes  $\geq 35$  (Accessories, page 968)

## NUKR .. A design cam followers

- are based on double row full complement cylindrical roller bearings without an integral flange between the two roller sets ([fig. 8](#))
- have the outer ring axially guided by the stud head and pressed-on flange ring via the roller sets
- have a sheet metal angle ring pressed into the outer ring shoulder on both sides, forming an effective labyrinth seal
- have a hexagonal recess at each end of the stud, enabling the cam follower to be held in place by a hexagonal key (Allen wrench) during mounting
- have a relubrication hole for a press-in grease fitting or an adapter from a centralized lubrication system in the centre of each hexagonal recess (*Accessories*, [page 968](#))
- accommodate relatively heavy axial loads that can occur because of skew or tilting

## PWKR ...2RS design cam followers

- are based on double row full complement cylindrical roller bearings ([fig. 9](#))
- have the outer ring axially guided by the stud head and pressed-on flange ring via the roller sets
- are fitted on both sides with an NBR contact seal, being integral with a sheet metal angle ring that is pressed into the outer ring shoulder, to press against the flange ring and the stud head
- have a hexagonal recess at each end of the stud, enabling the cam follower to be held in place by a hexagonal key (Allen wrench) during mounting
- have a relubrication hole for a press-in grease fitting or an adapter from a centralized lubrication system in the centre of each hexagonal recess (*Accessories*, [page 968](#))
- accommodate relatively heavy axial loads that can occur because of skew or tilting

## Cages

Cam followers, if not a full complement of rollers, are fitted with a sheet steel window-type cage that is roller centred ([fig. 10](#)).

For information about the suitability of cages, refer to *Cages*, [page 187](#).

## Accessories

SKF supplies accessories to enable reliable lubrication and location of SKF cam followers ([table 1](#)). Accessories, other than grease fittings and hexagonal nuts, must be ordered separately.

## Grease fittings

- are supplied with each cam follower as standard ([table 1](#)) and are the only ones to be used
- can be pressed into position
- are listed in [table 2, page 970](#) with their dimensions
- have heads that protrude from the stud head end by 1,5 mm for KR design cam followers of sizes 16 and 19

## Hexagonal nuts

- are supplied with each cam follower as standard ([table 1](#))
- are in accordance with ISO 4032 or ISO 8673
- are manufactured to strength class 8.8
- are zinc galvanized in accordance with ISO 4042
- are listed in [table 3, page 970](#) with their dimensions and recommended tightening torques

## VD1 plugs

- are used to plug the relubrication hole end in the stud of KR design cam followers of sizes 16 and 19 without designation suffix PPSKA, where:
  - relubrication is not required
  - there is no space for the head of the grease fitting
- must be ordered separately ([table 1](#))

## AP design adapters

- enable cam followers to be relubricated via a centralized lubrication system
- have a connection that accommodates, for example, 4 × 0,75 polyamide tubing in accordance with DIN 73378, as shown in [fig. 11](#), in which:
  - 1 Connection
  - 2 O-ring
  - 3 Adapter connection
  - 4 Female thread M10x1
  - 5 Polyamide tube
- must be ordered separately ([table 1](#))
- are listed in [table 4, page 970](#) with their dimensions

# Lubrication

SKF cam followers are supplied greased ([table 1, page 933](#)).

For general information, refer to *Lubrication*, [page 109](#).

## Relubrication requirements

Cam followers:

- should be relubricated regularly to achieve their full service life, even if the initial grease fill still has its full lubricating properties
- used in applications where there are light loads, relatively low speeds and clean surroundings can operate for long periods before relubrication is required
- that operate under contaminated and damp conditions at high speeds or at temperatures  $> 70\text{ }^{\circ}\text{C}$  ( $160\text{ }^{\circ}\text{F}$ ) require more frequent relubrication
- without a cage (full complement of rollers) require more frequent relubrication

KR design cam followers of sizes 16 and 19 with designation suffix PPSKA cannot be relubricated.

## Relubrication features

Cam followers can be relubricated via ducts inside the stud. Depending on series and size, there are up to three positions for relubrication ([fig. 12](#)):

- Positions 1 and 2 can be fitted with the grease fitting supplied with the cam follower.
- Position 3 should be used when relubricating via ducts in the adjacent components.
- For detailed information about the positions, refer to [product tables, page 978](#).
- For cam followers, sizes  $\geq 35$ , positions 1 and 2 can be connected to a centralized lubrication system (*Accessories*, [page 968](#)).
- Positions not used for relubrication should be closed by a grease fitting or a plug (*Accessories*).

## Temperature limits

The permissible operating temperature for cam followers can be limited by:

- the dimensional stability of the bearing rings and rollers
- the cage
- the seals
- the lubricant

Where temperatures outside the permissible range are expected, contact SKF.

### Bearing rings and rollers

SKF cam followers are heat stabilized up to at least 140 °C (280 °F).

### Cages

Steel cages can be used at the same operating temperatures as the bearing rings and rollers.

### Seals

The permissible operating temperature for seals depends on the seal material:

- NBR: -40 to +100 °C (-40 to +210 °F)  
Temperatures up to 120 °C (250 °F) can be tolerated for brief periods.
- PA66 sliding rings: -30 to +100 °C (-20 to +210 °F)

Typically, temperature peaks are at the seal lip.

### Lubricants

Temperature limits for greases used in SKF cam rollers are provided in [table 1, page 933](#). For temperature limits of other SKF greases, refer to *Selecting a suitable SKF grease*, [page 116](#).

When using lubricants not supplied by SKF, temperature limits should be evaluated according to the SKF traffic light concept ([page 117](#)).

## Speed limits

The limiting speed listed in the [product table](#) is a mechanical limit that should not be exceeded unless the bearing design and the application are adapted for higher speeds.

For additional information, refer to *Operating temperature and speed*, [page 130](#).

## Design considerations

### Attachment holes for studs

The holes in the adjacent part of machinery that will accommodate the stud or eccentric collar of a cam follower should be machined to tolerance class H7 $\oplus$ .

If the requisite tightening torque for the hexagonal nut ([table 3, page 970](#)) cannot be achieved or the cam followers are subjected to peak loads, the stud or eccentric collar should be mounted with an interference fit. The lead-in chamfer of the holes should be  $\leq 0,5 \times 45^\circ$ .

## Support surfaces

The flange ring that is pressed onto the stud shank should be axially supported:

- over its entire side face ([fig. 13](#))
- according to diameter  $d_1$  ([product table, page 978](#))
- with material that has a sufficiently high strength to accommodate the tightening torque ([table 3, page 970](#))

# Mounting

Cam followers can be attached to associated components (fig. 13) using the hexagonal nut (table 3, page 970) supplied with the cam follower. Spring washers, which are not supplied by SKF, serve to secure the nuts.

- To exploit the full load carrying capacity of cam followers, the nuts should be tightened to the recommended torque values (table 3).
- Where heavy vibrations occur, cam followers can be located using:
  - self-locking nuts in accordance with ISO 10511
  - special lock washers
 For self-locking nuts, a higher tightening torque must be applied. Follow the recommendations of the nut manufacturer.
- Cam followers, sizes  $\geq 22$ , have a hexagonal recess in the stud head and can be held in place by a hexagonal key (Allen wrench) while the nut is being tightened.
- Some small cam follower designs (sizes 16 and 19) have a slot in the stud head instead and can be held in place by a screwdriver. For additional information, refer to the illustrations in the product table, page 978.
- Depending on the mounting conditions, cam followers with an eccentric collar can be adjusted to the required eccentricity via the slot or the hexagonal recess.
- Do not hit the head of the stud as damage to the cam follower may result.

- SKF recommends positioning the lubrication hole in the stud head in the unloaded zone of the cam follower. The position of this hole corresponds to the SKF trade-mark on the head end of the stud.
- The lubrication hole in position 3 that is parallel and in line with the lubrication hole in the stud head (fig. 12, page 971) may be used to incorporate a locking device to prevent the stud from turning.
- When inserting a plug, it should be pressed into place using a mandrel (fig. 14).

SKF sensor bearing units are used to monitor accurately the status of rotating or linear components and are:

- compact
- robust and reliable
- simple and ready-to-mount

Sensor-integrated solutions engineered by SKF have been well proven in a variety of industrial and automotive applications, such as electric motors, electric vehicles, road rollers, tractors, forklifts and conveyors. Typical uses include:

- motor management
- steering
- speed and position sensing
- measurement of angular position

## Motor encoder units

Monitoring the status of rotating components accurately is essential for many applications. This is particularly true for AC motors that require encoders to measure the speed and the direction of rotation continuously.

SKF motor encoder units ([fig. 1](#)) combine active sensor technology with an SKF Explorer deep groove ball bearing and are:

- able to provide a signal resolution ranging from 32 to 80 digital pulses per revolution
- compact only 6,2 mm wider than the corresponding standard deep groove ball bearing ([fig. 2](#))
- ready-to-mount and can be mounted at either bearing position in an AC motor
- available for shaft diameters ranging from 15 to 45 mm

Fig. 1

## Designs and variants

SKF motor encoder units are compact, integrated units consisting of (fig. 3):

- an SKF Explorer deep groove ball bearing in the 62 series with a snap ring groove in the outer ring and an RS1 contact seal (*Single row deep groove ball bearings, page 241*)
- an impulse ring
- a sensor body
- a connecting cable

The impulse ring, which attaches to the inner ring of the bearing, is a composite magnetized ring that contains between 32 and 80 north and south poles. The number of poles depends on the size of the bearing. The sensor body, which is attached to the outer ring, protects the patented SKF Hall effect cell. The multi-wire connecting cable extends in the radial direction.

The bearing is protected by a contact seal on one side. On the opposite side of the bearing, the impulse ring and sensor body create an effective labyrinth seal to keep lubricant in and solid contaminants out of the bearing.

## Sensor technology

SKF motor encoder units use a compact and robust sensor that produces an incremental encoder signal. The sensor is accurate down to zero revolutions per minute. An integrated active circuit (requiring an external voltage supply) in the sensor body contains two Hall effect cells that produce an output signal consisting of two square waves (fig. 4).

The signals can be interpreted by motor controllers in different ways:

- The direction of rotation can be determined from the phase shift, when the rising edge of a signal first appears.
- Low speeds can be determined by measuring the time between two electrical events, such events being the rising and falling edge on either square wave.
- High speeds can be measured by counting the number of electrical events within a given time period.

The two square waves are 90° out of phase with each other. This phase shift changes sign with the direction of rotation. fig. 4 shows the general specifications of the signal. The presence of two signals in quadrature enables a processing unit to multiply the number of angular position increments per revolution. For example, using a standard SKF sensor bearing with 64 pulses per revolution and a standard electronic interface that can detect the rising (Low/High) and falling (High/Low) times of each of the two

signals, it is possible to obtain 256 electrical events per revolution, which translates to an angular resolution of  $1,4^\circ$  (fig. 4, page 989).

SKF motor encoder units provide accurate and reliable signals for effective motor control and are 100% tested for period accuracy, duty cycle and phase shift during manufacture.

### Cable connection

SKF motor encoder units are available as standard with one of the following:

- a free cable end with an output signal consisting of two square waves, designation suffix 008A (fig. 5)
- an AMP Superseal™ connector (AMP Nos. 282106-1 and 282404-1), designation suffix 108A (fig. 6)

Standard cable lengths are listed in the [product table, page 1002](#). For alternative connectors or cable lengths, contact SKF.

### Lubrication

SKF motor encoder units are:

- filled, under clean conditions, with a high-quality grease (table 2, page 245) that is suitable for the most common operating conditions of electric motors
- virtually maintenance-free

The grease life in the bearing can be calculated according to the method described under *Grease life for capped bearings*, page 246.

### Motor encoder units for extreme operating conditions

Magnetic sensors have temperature and motor power limits. For applications where magnetic sensors are not practical, high-performance inductive technology can be used instead. Inductive sensors use coils to sense the rotation of a specially designed induction tooth ring. For additional information about motor encoder units for extreme operating conditions, contact SKF.

## Product data

### Requirements for the receiving interface

The receiving interface must be able to process the signals, which are provided via open collector circuits (fig. 7). Output signal features are listed in table 1. The phase shift is the delay between the two signals' rise events (fig. 4, page 989). It is 1/4 of the period, or 90 electric degrees. The duty cycle value is the high state of the signal compared to the full period (fig. 4). It is nominally 50%.

### Power supply

SKF motor encoder units require a regulated voltage supply, which can range from 5 to 18 V DC. For applications above 18 volts, contact SKF.

### Resistors

Pull-up resistors (table 2) should be placed between the voltage supply and the conductors for the output signals to limit the output current to 20 mA. The application load resistance between the ground line and the conductors for the output signals should be at least 10 times higher than the resistance of the pull-up resistor. This helps to keep the output signals readable.

### Detecting direction of rotation

A positive phase shift corresponds to signal B rising before signal A and indicates the inner ring rotating clockwise when viewed from the sensor side.

### Electromagnetic compatibility

SKF motor encoder units can be used in systems operating in very arduous electromagnetic environments as described in the international standard IEC 61000-6-2.

### High-performance filtering

All standard SKF motor encoder units are protected with high-performance filtering so that they can adapt to the electric environment typically found in industrial and automotive applications:

- Units with a free cable end have the filter included in the overmoulding on the cable.
- Units with an AMP Superseal™ connector have the filter integrated in the connector.

## Loads

For information about minimum load and equivalent bearing loads, refer to *Loads*, [page 254](#).

The required minimum load factor  $k_r$  and calculation factor  $f_0$  are listed in the [product table, page 1002](#).

## Temperature limits

SKF motor encoder units have been tested successfully under various speeds and loads:

- 500 hours at 125 °C (255 °F), with intermittent peaks of up to 10 minutes at 150 °C (300 °F)
- 100 hours at -40 °C (-40 °F)

Where other temperatures are expected, contact SKF.

Fig. 8

### Radial notch in the housing

Fig. 9

Fig. 10

### Recommended load transmission

## Permissible speed

The permissible operating speed is limited by the contact seal in the bearing. The sensor can accurately detect speeds from zero revolutions per minute up to the limiting speed listed in the [product table](#), [page 1002](#).

## Design considerations

In principle, SKF motor encoder units can be incorporated in designs in the same way as SKF deep groove ball bearings. Some specific recommendations are described below. For additional information about electric motor applications, refer to the SKF handbook *Rolling bearings in electric motors and generators*.

### Cable outlet

The cable emerges radially from the motor encoder unit. A sufficiently dimensioned cable duct must be provided in the bearing housing or housing cover. The radial notch in the housing should have a width in the circumferential direction of 15 to 20 mm ([fig. 8](#)).

## Motor encoder units in the non-locating bearing position

SKF recommends using motor encoder units in the non-locating bearing position ([fig. 9](#)). However, there is a risk that the outer ring can spin in the housing bore, especially if vibration is a factor. Therefore, SKF recommends placing an O-ring in the snap ring groove to help prevent the outer ring from spinning, which could otherwise damage the cable.

## Motor encoder units in the locating bearing position

When using motor encoder units in the locating bearing position, the impulse ring, sensor body and connecting cable should not be subjected to any axial load, whenever possible. When the bearing is subjected to axial loads that act in both directions, the motor encoder unit should be mounted in such a way that the heavier axial load is transmitted to the bearing outer ring side face opposite the sensor ([fig. 10](#)).

Motor encoder units can be located axially in the housing in different ways:

- with a snap ring in the outer ring and a cover bolted to the housing ([fig. 11](#))
- with a spacer sleeve and a snap ring in the housing ([fig. 12](#))
- with a cover engaging the outer ring ([fig. 13](#))

Motor encoder units with  $d \leq 25$  mm can only be located axially via a snap ring in the outer ring.

## Motor encoder units in floating bearing arrangements

When using motor encoder units in floating bearing arrangements ([page 76](#)), the outer ring should be prevented from spinning by placing an O-ring in the snap ring groove. The motor encoder unit should be mounted in such a way that the axial load acts on the bearing outer ring side face opposite the sensor.

# Mounting

SKF motor encoder units must be handled with care to avoid damaging the bearing, sensor and connecting cable. Never apply any force on the cable, cable outlet, sensor body or impulse ring.

On request, SKF can provide assistance in optimizing the mounting and connecting processes.

## Mounting a unit on a shaft

Motor encoder units are typically mounted on a shaft with an interference fit. They can be pressed onto the shaft by applying a mounting force via a mounting sleeve or dolly abutting the inner ring side face (fig. 14). To facilitate mounting, the bearing inner ring can be heated:

- Use a temperature-controlled electric hotplate.
- Do not heat the unit above 80 °C (175 °F).
- Place the bearing on a mandrel to heat the inner ring effectively (fig. 15).
- Position the bearing so that the seal is in the lower position to avoid grease leaking out of the bearing.
- Do not use induction heaters as damage to the electronic components may result.

Fig. 14

Mounting force applied via a dolly abutting the inner ring side face

Fig. 15

Bearing on a mandrel to heat the inner ring

## Mounting a unit into a housing

When motor encoder units have to be mounted into a housing with an interference fit, they can be pressed into the housing or the housing should be heated. The mounting force should be applied via a mounting sleeve or dolly abutting the outer ring side face or via a snap ring fitted on the outer ring (fig. 16).

In typical electric motor applications, the bearing can be moved into position by using bolts to pull the motor shield and cover together (fig. 17).

## Cable connection

The cable should be protected by a duct to prevent it from making sharp turns, being pinched or making contact with any moving parts. To avoid any interference with the sensor signal, do not place the connector near other power cables or wires.

# Roller encoder units

SKF roller encoder units (fig. 18, table 3) are plug-and-play sensor bearing units designed for applications with outer ring rotation.

The encoder units:

- incorporate a sealed 6201 SKF Explorer deep groove ball bearing, which is lubricated for the life of the bearing
- can be easily integrated into pulleys, cams, rollers, or wheels to provide a compact outer ring rotation encoder assembly
- can be supplied, on request, complete with customized gears, wheels or pulleys

## Sensor technology

SKF roller encoder units use similar sensors as SKF motor encoder units (page 988).

They provide two signals, which can be used to determine relative position, speed, acceleration and direction of movement. The requirements for the receiving interface are the same as for SKF motor encoder units.

# Steering encoder units

SKF steering encoder units (fig. 19, table 4) are steering input devices for steer-by-wire systems that combine reliable encoder technology with the simplicity of plug-and-play component packaging.

The detailed design of the units is based on well-proven SKF technologies. The units consist of:

- a sealed SKF Explorer deep groove ball bearing for long service life and reliable performance
- bearing encoder technology for precise monitoring
- a friction torque device, which provides feedback to the operator by providing adequate resistance in the steering wheel
- a mechanical interface for mounting
- a shaft to connect the steering wheel

The units reliably fulfil the demands of industrial and off-highway vehicle steer-by-wire systems and:

- do not require any adjustment
- do not require relubrication during their expected service life and are virtually maintenance-free
- are supplied ready-to-mount (connection to a steer-by-wire system is achieved by plugs)

## 17 Sensor bearing units

### Sensor technology and electrical data

SKF steering encoder units use sensors to track the movement of a steering wheel. They contain two sets to provide redundancy. The sensors:

- are magnetic
- are non-contact and incremental
- do not wear
- are protected from external influences
- are designed to provide maximum service life

SKF steering encoder units comply with the safety requirements of safety-related control systems in accordance with ISO 13849.

SKF steering encoder units provide two independent sets of square wave signals ([fig. 20](#)) via open collector circuits. They require:

- a regulated voltage supply, which can range from 5 to 24 V DC
- pull-up resistors ([table 2, page 991](#)) that should be placed between the voltage supply and the conductors for the output signals to limit the output current to 20 mA

The application load resistance between the ground line and the conductors for the output signals should be at least 10 times

higher than the resistance of the pull-up resistor. This keeps the output signals readable.

### Units providing absolute position information

SKF can provide customized steering units for applications where a combination of absolute position information, variable steering feel, and active end stops are required. For additional information, contact SKF.

## Rotor positioning sensor bearing units

Synchronous motors require a sensor that provides the position of the rotor with a high accuracy, to enable accurate motor torque control and to achieve maximum efficiency and dynamics. These motors use either direct drive or sine wave control. SKF rotor positioning sensor bearing units ([fig. 21, table 5](#)) can contribute to optimized motor efficiency for both systems.

### Units for sine wave or vector control

- provide the shaft angle position in real time throughout the entire motor speed range
- provide a signal ([diagram 1](#)) comparable to the one provided by a resolver and can therefore be used by the motor controller's software
- communicate the shaft angle position via a sine/cosine wave signal
- are more compact and cost-effective than inductive resolvers
- are easy to mount ([Mounting, page 994](#))
- do not require special shaft or housing accuracy in comparison with inductive resolvers ([Design considerations, page 993](#))

SKF can adapt the electronics to comply with the interface of the application.

# Rotor positioning bearings

SKF Rotor positioning bearings (fig. 22, table 6) are customized units with optimized mechanical integration between a magnetic impulse ring and a bearing in an application. The integrated units:

- allow the use of nearly all bearing types
- allow high speeds and temperatures
- generate strong magnetic impulses that are related to the rotor angular position
- can deliver the magnetic field in the axial or radial direction, on a through shaft or at the end of a shaft
- are very robust under severe operating conditions as a result of their high magnetic field strength

## Applications

- absolute angular position information for electric motor control in, for example:
  - belt-driven starter generators
  - traction motors
  - e-superchargers and e-turbochargers
- shaft speed detection or low-resolution angular position in, for example:
  - crankshafts
  - transmission shafts

SKF high temperature bearings are designed to deliver increased reliability, reduced complexity and decreased environmental impact in operating temperatures up to 350 °C (660 °F). Because SKF high temperature bearings correspond to the ISO dimensions of grease-lubricated bearings, production efficiencies and cost savings can be realized with a simple change to the SKF bearing solution.

The environmental benefits of SKF high temperature bearings are so significant in many applications that they are included in the “SKF Beyond Zero” product portfolio.

## Bearing benefits and features

### • Reduced total operating cost

The bearings are designed to maintain the radial clearance needed for high temperature operation and so will not seize, even

when they cool rapidly, and therefore provide a long service life.

### • Excellent performance under severe conditions:

- hot conditions
- dry environments
- low rotational speeds

### • Reduced environmental impact

### • Reduced machine design complexity

Additionally, the benefits and features of high temperature bearings include (fig. 1):

### 1 No need for relubrication

All variants, except open (without shields) VA201 deep groove ball bearings, are lubricated for the life of the bearing with graphite-based high temperature lubricants. Open VA201 bearings require relubrication (*Relubrication and running in*, page 1014).

Fig. 1

## Bearing benefits and features

## 2 Simple replacement

The boundary dimensions are the same as those of standard bearings.

## 3 Operating temperature up to 350 °C (660 °F)

The internal radial clearance and the lubricant are optimized for operation at high temperatures.

## 4 Protection against solid contamination

- Shields (designation suffix 2Z) protect the deep groove ball bearing.
- Shields and flingers (designation suffix 2F) protect the insert bearing.

## 5 Improved running in

The entire bearing surface is manganese phosphate coated.

With many variants, all surfaces of the bearing and, where applicable, shields and flingers are manganese phosphate coated to enhance adhesion of the lubricant to the metal and provide some protection against corrosion.

## Typical applications

- metals industry (cooling beds, roller tables, furnaces)
- food and beverage industry (continuous baking ovens, wafer baking ovens)
- automotive industry (paint lines, heat treatment ovens)
- glass industry (glass tableware or flat glass manufacturing processes)
- construction industry (tiles, mineral wool manufacturing)

## Customized bearings

In addition to high temperature bearings corresponding to ISO standards, SKF offers an assortment of customized high temperature bearings ([fig. 5, page 1008](#)).

These bearings are customized for use in applications such as:

- automatic wafer baking ovens in the food and beverage industry
- industrial furnaces
- chains

For additional information, contact SKF.

## Lubrication solutions

SKF high temperature bearing designs and variants incorporate various graphite-based lubrication solutions, including:

- lubricating paste composed of a poly-alkylene glycol/graphite mixture
- graphite cages (segmented or coronet)

For an overview of lubricant types, and other characteristics, for high temperature deep groove ball bearings and insert bearings, refer to [table 1, page 1009](#), and [table 2, page 1010](#).

During operation, the graphite maintains a very thin film on the bearing's raceways and rolling elements to reduce wear significantly. Graphite ages at a much higher temperature than oil and grease, and therefore does not lose its lubricating properties at the high temperatures at which it is recommended for use, so the need for relubrication is eliminated.

## Assortment

The SKF standard assortment of high temperature bearings and bearing units corresponding to ISO standards includes:

- Deep groove ball bearings ([fig. 2](#))
- Insert bearings (Y-bearings, [fig. 3](#))
- Ball bearing units ([fig. 4](#), [skf.com/go/17000-18](http://skf.com/go/17000-18))
  - Zinc chromate plummer block units
  - Zinc chromate square flanged units
  - Zinc chromate oval flanged units

The assortment includes variants that contain food-grade lubricants registered by NSF as category H1 (lubricant acceptable with incidental food contact, for use in and around food processing areas). The NSF registration confirms the lubricant fulfils the requirements listed in the US Food and Drug Administration's guidelines under 21 CFR section 178.3570.

# Deep groove ball bearings for high temperature applications

SKF deep groove ball bearings for high temperature applications correspond in design to standard single row deep groove ball bearings of the same size. They have no filling slots and can accommodate axial loads in addition to radial loads (*Loads and selecting bearing size*, [page 1012](#)).

The entire surface of the bearing and shields are manganese phosphate coated to enhance adhesion of the lubricant to the metal and improve the running-in properties of the bearing.

The radial internal clearance is a multiple of C5 to prevent the bearings from seizing, even when they cool rapidly.

## Designs and variants

The SKF assortment of deep groove ball bearings for high temperature applications ([fig. 6](#)) provides solutions for various combinations of operating temperature and speed.

The lubrication type, maximum operating temperature, limiting speed, maintenance requirements and all other primary characteristics of the variants within the assortment are listed in [table 1](#).

## Sealing solutions

High temperature deep groove ball bearings can be protected from contamination by either integrated shields, external shields or a combination of both.

For high temperature bearings, metallic shields are the primary recommendation where a capping device with low complexity is required. The shields:

- prevent the ingress of solid contaminants into the bearing
- are non-contacting
- generate no friction
- do not wear
- are particularly well suited for high temperatures because of their material and design

## Integrated shields

High temperature deep groove ball bearings with designation suffix 2Z have integrated shields, but the VA201 variant is also available as an open bearing ([fig. 6](#)).

## External shields

In some cases, integrated shields are insufficient and additional external shields should be considered, such as:

- Nilos rings ([fig. 7](#))
- SKF sealing washers ([fig. 8](#))

For additional information about sealing solutions, refer to *External sealing*, [page 194](#), and *Seals* ([skf.com/seals](http://skf.com/seals)).

**NOTE:** Because of the large radial clearance for high temperature deep groove ball bearings, special attention should be given to the design of the sealing arrangement.

## Custom-made seals

In cases where neither integrated nor external shields are applicable, SKF can provide custom-made seals for operating temperatures up to 250 °C (480 °F). These seals are usually made of PTFE (polytetrafluoroethylene) thermoplastics.

To further improve sealing systems that incorporate custom-made seals, it is preferable to use a wear sleeve such as the *SKF Speedi-Sleeve* ([skf.com/seals](http://skf.com/seals)). This improves the seal counterface condition without the need for re-machining. For additional information, contact SKF.

### ⚠ WARNING

PTFE seals exposed to an open flame or temperatures above 300 °C (570 °F) are a health and environmental hazard! They remain dangerous even after they have cooled.

Read and follow the safety precautions on [page 197](#).

# Insert bearings for high temperature applications

Except for the cage and seals, SKF insert bearings (Y-bearings) for high temperature applications correspond in design to standard insert bearings with grub screws in the YAR 2-2F series (page 342).

The grub (set) screws in the inner ring enable quick and easy mounting/dismounting. The bearings have a shield and a flinger on both sides to prevent the ingress of solid contaminants into the bearing.

The entire surface of the bearing and the shields are manganese phosphated to enhance adhesion of the lubricant to the metal and improve the running-in properties of the bearing. The flingers are treated by pickling.

The radial internal clearance is a multiple of C5 to prevent the bearings from seizing, even when they cool rapidly.

## Designs and variants

The SKF assortment of insert bearings for high temperature applications (fig. 9) provides solutions for various combinations of operating temperature and speed.

The lubrication type, maximum operating temperature, limiting speed, maintenance requirements and all other primary characteristics of the variants within the assortment are listed in table 2.

## Sealing solutions

SKF high temperature insert bearings are capped on both sides with a shield and a flinger that create a narrow gap-type labyrinth seal (designation suffix 2F).

For high temperature bearings, metallic shields are the primary recommendation where a capping device with low complexity is required. The shields:

- prevent the ingress of solid contaminants into the bearing
- are non-contacting
- generate no friction
- do not wear
- are particularly well suited for high temperatures because of their material and design

# Loads and selecting bearing size

The bearing size is selected based on the basic static load rating  $C_0$  from the relevant product table.

For an equivalent static bearing load  $P_0$ , the selected bearing must have a  $C_0$  value  $\geq$  the value of the requisite basic static load rating  $C_{0req}$  (table 5).

The values in table 5 are valid only when  $P_0 = F_r$ . That is, when:

- $F_a < 0,8 F_r$
- $F_a < 0,15 C_0$

# Design considerations

## Location of bearings

### Deep groove ball bearings

The selection of shaft and housing fits depends on the bearing operating condition and bearing size. An appropriate fit is needed to locate the shaft, provide satisfactory support and allow for thermal expansion up to the stated maximum operating bearing temperature (table 6).

### Insert bearings

For moderate loads ( $0,035 C < P \leq 0,05 C$ ), the shaft seats should be machined to an h7Ⓔ tolerance. For light loads and low speeds, an h8Ⓔ shaft tolerance is sufficient.

## Operating environment

SKF high temperature bearings are designed to provide solutions to common issues in high temperature applications. In addition to operations involving high temperatures and low rotational speeds, it is important to consider environmental conditions in the process area.

Since high temperature bearings are supplied without preservative oils and must be used without grease or oil lubrication, the anti-corrosion property of the bearings is limited. Therefore, the bearings should be used in a dry environment or with a proper sealing solution to keep the bearings dry.

## Axial displacement

To accommodate axial displacement, the shaft at the non-locating bearing position of high temperature insert bearings should be provided with one or two grooves, 120° apart, to engage a modified grub screw:

- Hexagon socket grub (set) screws with a dog point, in accordance with ISO 4028, but with a fine thread according to table 10, page 357. The grub screw should be secured by a nut and a spring or star lock washer (fig. 10).

The screws and groove(s) accommodate changes in shaft length and prevent the shaft from turning independently of the bearing. The sliding surfaces between the shaft and inner ring and those in the shaft grooves should be coated with a lubricant paste suitable for the operating temperature.

# Relubrication and running in

## Relubrication

All SKF high temperature bearings are lubricated for the life of the bearing, except open VA201 deep groove ball bearings, which require relubrication.

The general recommendation for an open VA201 bearing is to investigate the quality of the lubricating paste in the bearing every six months. If there is no longer a film of dry lubricant on the raceways, indicated by a bright metallic shiny track, remove residues of the old lubricant with a solvent and, when dried, replenish the bearing with lubricating paste.

## Running in

VA201 bearings operating at temperatures below 200 °C (390 °F) and at speeds below 25% of the limiting speed ([product tables](#), [page 1016](#) and [page 1020](#)) require running in. Open VA201 deep groove ball bearings operating under these conditions also require running in after relubrication.

Running in requires the bearing to be operated at a temperature of at least 200 °C (390 °F) for a minimum of 48 hours.

# Mounting

SKF high temperature deep groove ball bearings should always be hot mounted to reduce the mounting force and the risk of breaking the graphite lubricant (VA208 and VA228 variants). An induction heater is the preferred choice to heat the bearing during mounting.

Submerging the bearing in hot oil is not recommended because the oil remaining in the bearing might carbonize later during operation.

Do not use impact mounting methods that could damage the bearing and prevent proper functionality.

# Designation system

Refer to the *Designation system* of the relevant standard bearing:

- deep groove ball bearings, [page 258](#)
- insert bearings, [page 364](#)

Designation suffixes used with SKF bearings for high temperature applications are explained in the following:

- 2F** Insert bearing for high temperature applications, with grub screw locking, shield and flinger on both sides
- 2Z** Deep groove ball bearing for high temperature applications, shield on both sides
- VA201** Bearing for high temperature applications, with a stamped steel cage, manganese phosphate coated rings and rolling elements, radial clearance of multiples of C5, and lubricated with a polyalkylene glycol/graphite mixture
- VA208** Bearing for high temperature applications, with a segmented cage made of graphite, manganese phosphate coated rings and rolling elements, and radial clearance of multiples of C5
- VA228** Bearing for high temperature applications, with a coronet cage made of graphite, manganese phosphate coated rings and rolling elements, and radial clearance of multiples of C5
- W** Insert bearing for high temperature applications, without lubrication hole(s)

SKF bearings with Solid Oil are designed for use in applications where high levels of moisture and incidental contact with water and other contaminants are real issues.

Bearings with Solid Oil are lubricated for the life of the bearing and cannot be relubricated.

Solid Oil:

- is an oil saturated, polymer material
  - moulded into the bearing, forming very narrow gaps between the rolling elements, raceways and cage(s), enabling the bearing to rotate freely
  - having a porous structure, with millions of micro-pores that retain the lubricating oil by surface tension
- virtually fills all of the free space in the bearing
- releases oil into the narrow gaps, during operation, providing effective minimum quantity lubrication

- **Resists washout**

- Solid Oil cannot be washed out and virtually fills all free space, limiting the amount of wet contamination that can enter the bearing.
- Water cannot mix with the oil or Solid Oil polymer.

- **Virtually eliminates lubricant leakage**

- Solid Oil retains oil in the bearing.
- Integral bearing seals further increase the oil retention.

- **Protects against the ingress of contaminants**

- Close osculation between Solid Oil and the rolling elements and raceways significantly reduces the ingress of contaminants.
- Solid Oil provides additional support for integral bearing seals.

## Bearing features

- **Long service life**

- An increase in operating temperature pushes the oil toward the surface of the polymer material, supporting consistent lubricant supply. During shutdown, any excess oil is re-absorbed back into the polymer material.

- **Extended lubricant life**

- With Solid Oil bearings, a large amount of oil is available (two to four times more compared to conventional grease fill).
- The Solid Oil polymer structure eliminates lubricant churning.
- Solid Oil is a high-quality synthetic oil that resists oxidation.

## Designs and variants

The SKF standard assortment of bearings and bearing units with Solid Oil (fig. 1) includes:

- Deep groove ball bearings
- Spherical roller bearings
- Insert bearings and ball bearing units
- Tapered roller bearings
- Cylindrical roller bearings
- Self-aligning ball bearings

On request, SKF can supply other bearing types with Solid Oil to meet the needs of a particular application, except for CARB toroidal roller bearings which are unsuitable for use with Solid Oil. Bearings fitted with a large-volume cage are not suitable for Solid Oil because there is too little free space inside the bearing.

## Solid Oil variants

- Standard variant (designation suffix W64, table 1):
  - contains a high-quality synthetic oil
  - meets the needs of most applications
- Food-grade variant (designation suffix W64F, table 1):
  - contains an oil registered by NSF as category H1
  - meets the needs of food applications

## Sealed bearings

- with integral contact seals are strongly recommended in wet environments
- with Solid Oil increase the sealing effectiveness, as the Solid Oil supports the seals axially, preventing them from deflecting and opening under pressure

For information about sealing options, contact the SKF application engineering service.

Where carbon steel bearings are exposed to wet environments, additional external seals are recommended to protect the bearing's external surfaces from corrosion.

## Loads

### Load carrying capacity

The basic dynamic and static load ratings for bearings with Solid Oil are the same as for corresponding SKF standard bearings.

## Temperature limits

The permissible operating temperature for bearings with Solid Oil can be limited by:

- the dimensional stability of the bearing rings and rolling elements
- the cage(s)
- the seals
- the Solid Oil

For limits of bearing rings, rolling elements, cage(s) and seals, refer to *Temperature limits* of the relevant product section of the standard bearing.

The relevant limits for Solid Oil are listed in [table 1](#), [page 1025](#).

Where temperatures outside the permissible range are expected, contact SKF.

## Speed limits

The recommended speed values for bearings and bearing units with Solid Oil ([table 2](#)), operating in an ambient temperature of 20 °C (70 °F), are limited by the maximum continuous operating temperature of 85 °C (185 °F). Ambient temperature is the temperature closest to the bearing position, not necessarily room temperature.

For bearing types or variants not listed in [table 2](#), contact the SKF application engineering service.

For ambient temperatures above 20 °C (70 °F), the speed limit should be reduced using the reduction factor  $f_T$  ([diagram 1](#)).

### Calculation example

A deep groove ball bearing 6208/W64 is to operate at an ambient temperature of 50 °C (120 °F). What is the reduced speed limit?

#### 1 Recommended speed limit for 20 °C (70 °F) ambient temperature

- From [table 2](#): speed value  
 $nd_m = 300\,000$  mm/min (single row deep groove ball bearing with a stamped metal cage)
- Dimensions:  $d = 40$  mm,  $D = 80$  mm  
 $n = 300\,000 / d_m$   
 $= 300\,000 / (0,5 (40 + 80))$   
 $= 5\,000$  r/min

#### 2 Reduction for 50 °C (120 °F) ambient temperature

- From [diagram 1](#): speed reduction factor  
 $f_T \approx 0,53$   
 $n_{\text{reduced}} = 5\,000 f_T$   
 $= 5\,000 \times 0,53$   
 $= 2\,650$  r/min

Table 2

# Friction characteristics

The friction characteristics of a bearing with Solid Oil correspond to the relevant SKF standard bearing except that the Solid Oil polymer filling adds a fixed friction.

# Designation system

Refer to *Designation system* in the relevant product section of the standard bearing.

The designation suffixes used to identify bearings with Solid Oil are:

**W64** Synthetic base oil type, standard variant

**W64F** Synthetic base oil type, NSF H1 approved for food applications

# Mounting

If a bearing with Solid Oil is to be hot mounted, it should be heated to a maximum of 120 °C (250 °F) by using an induction heater.

Heating plates or heated oil baths should not be used.

Electric motors, generators and associated equipment are at risk when an electric current passes through their bearings. This can damage the contact surfaces of rolling elements and raceways in the bearings (electrical erosion) and rapidly degrade the grease. An additional risk in electric motors and generators comes from high frequency currents caused by the inherent stray capacitance. The risk of damage increases where the application uses a frequency converter. INSOCOAT bearings:

- are designed to prevent electric current from passing through the bearing
- have the external surfaces of either their inner or outer ring coated with an insulating aluminium oxide layer, by applying a sophisticated plasma-spray process for an outstanding quality finish
- are a very cost-effective solution compared with other insulation methods

## Bearing features

- **Protection against electrical erosion**  
With insulating properties integrated into the bearing, INSOCOAT bearings can improve reliability and increase machine uptime by virtually eliminating the problem of electrical erosion.
- **High electrical resistance**  
The aluminium oxide coating provides a minimum electrical resistance of 200 MΩ and can withstand voltages up to 3 000 V DC.
- **Consistent electrical performance**  
Plasma-spray coatings are normally hygroscopic and, therefore, vulnerable to penetration caused by condensation. To protect against this effect, INSOCOAT bearings are treated with a unique sealant.

## Assortment

The standard assortment of INSOCOAT bearings (fig. 1 and fig. 2) listed here constitutes the most commonly used sizes and variants of:

- single row deep groove ball bearings
- single row cylindrical roller bearings

For bearing types and sizes not listed in the product tables, contact SKF.

For applications where smaller bearings than those listed are needed, SKF recommends using SKF Hybrid bearings (*Hybrid bearings*, page 1043).

In addition to the standard assortment, SKF can supply special INSOCOAT bearings and bearing units with complex ring geometries (fig. 3), such as:

- four-point contact ball bearings
- flanged tapered roller bearings
- tapered roller bearing units (TBU)
- traction motor bearing units

For availability and detailed information, contact SKF.

## Designs and variants

### INSOCOAT bearings with a coated outer ring

INSOCOAT bearings typically have the external surfaces of the outer ring coated with aluminium oxide (fig. 1). These bearings are identified by the following designation suffixes:

- VL0241 – standard layer
- VL0246 – advanced layer for higher electrical resistance

For availability, contact SKF.

# INSOCOAT bearings with a coated inner ring

INSOCOAT bearings that have the external surfaces of the inner ring coated with aluminium oxide (fig. 2, page 1031) provide enhanced protection against high frequency electric currents. These bearings are identified by the following designation suffixes:

- VL2071 – standard layer
- VL2076 – advanced layer for higher electrical resistance

For availability, contact SKF.

## Capped bearings

Some INSOCOAT deep groove ball bearings can be supplied capped (*Capped bearings*, page 242). For availability, contact SKF.

## Cages

SKF INSOCOAT deep groove ball bearings are fitted with one of the following cages:

- a stamped steel cage, riveted, ball centred (no designation suffix)
- a machined brass cage, riveted, ball centred (designation suffix M)

For additional information, refer to *Cages*, page 249.

SKF INSOCOAT cylindrical roller bearings are fitted with one of the following cages:

- a glass fibre reinforced PA66 cage, window-type, roller centred (designation suffix P)
- a machined brass cage, riveted, roller centred (designation suffix M)
- a machined brass cage, window-type, inner or outer ring centred (depending on bearing design) (designation suffix ML)

For additional information, refer to *Cages*, page 502.

When used at high temperatures, some lubricants can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to *Cages*, page 187.

## Loads

For recommendations about minimum load, axial load carrying capacity and equivalent bearing loads, refer to *Loads* of the relevant standard bearing:

- deep groove ball bearings, [page 254](#)
- cylindrical roller bearings, [page 509](#)

The required INSOCOAT bearing specific values and factors are listed in the relevant product tables:

- *INSOCOAT deep groove ball bearings*, [page 1036](#)
  - basic static load rating  $C_0$
  - calculation factors  $f_0$  and  $k_r$
- *INSOCOAT cylindrical roller bearings*, [page 1038](#)
  - calculation factor  $k_r$
  - reference speed

## Temperature limits

The permissible operating temperature for INSOCOAT bearings can be limited by:

- the dimensional stability of the bearing rings and rolling elements
- the cage
- the lubricant

Where temperatures outside the permissible range are expected, contact SKF.

### Bearing rings and rolling elements

SKF INSOCOAT bearings are heat stabilized up to at least 150 °C (300 °F).

### Cages

Steel or brass cages can be used at the same operating temperatures as the bearing rings and rolling elements. For temperature limits of PA66 cages, refer to *Polymer cages*, [page 188](#).

### Lubricants

For temperature limits of SKF greases, refer to *Selecting a suitable SKF grease*, [page 116](#).

When using lubricants not supplied by SKF, temperature limits should be evaluated according to the SKF traffic light concept ([page 117](#)).

## Permissible speed

The speed ratings in the product tables (*INSOCOAT deep groove ball bearings*, [page 1036](#), and *INSOCOAT cylindrical roller bearings*, [page 1038](#)) indicate:

- the **reference speed**, which enables a quick assessment of the speed capabilities from a thermal frame of reference
- the **limiting speed**, which is a mechanical limit that should not be exceeded unless the bearing design and the application are adapted for higher speeds

For additional information, refer to *Operating temperature and speed*, [page 129](#).

SKF recommends oil lubrication for bearings with a ring centred cage (designation suffix ML). When these bearings are grease lubricated, the  $nd_m$  value is limited to  $\leq 250\,000$  mm/min.

where

$$d_m = \text{bearing mean diameter [mm]} \\ = 0,5 (d + D)$$

$$n = \text{rotational speed [r/min]}$$

# Design considerations

## Abutment dimensions

To maximize the effectiveness of the insulation, SKF recommends the following guidelines for dimensioning the shaft and housing shoulders (fig. 5):

- Bearings with a coated outer ring (designation suffix VL0241 or VL0246): housing abutment diameter  $\geq D_{a \min}$
- Bearings with a coated inner ring (designation suffix VL2071 or VL2076): shaft abutment diameter  $\leq d_{a \max}$

The values for  $D_{a \min}$  and  $d_{a \max}$  can be obtained from the product tables:

- *INSOCOAT deep groove ball bearings*, [page 1036](#)
- *INSOCOAT cylindrical roller bearings*, [page 1038](#)

## Mounting

During mounting, INSOCOAT bearings should be handled in the same way as standard bearings.

When using an induction heater for bearings with a coated inner ring (designation suffix VL2071 or VL2076), use a protective sleeve or an additional plastic support block.

In cases where springs are used to apply preload to deep groove ball bearings or lock nuts are used for axial clamping, SKF recommends inserting a steel spacer ring between the bearing and the preload or locking device (fig. 6).

The values for  $d_{a \min}$  and  $d_{a \max}$  can be obtained from the product tables:

- *INSOCOAT deep groove ball bearings*, [page 1036](#)
- *INSOCOAT cylindrical roller bearings*, [page 1038](#)

## Designation system

Refer to *Designation system* of the relevant standard bearing:

- deep groove ball bearings, [page 258](#)
- cylindrical roller bearings, [page 514](#)

The designation suffixes used to identify INSOCOAT bearings are explained in the following.

**VL0241** External surfaces of the outer ring are coated – standard layer.

**VL0246** External surfaces of the outer ring are coated – advanced layer.

**VL2071** External surfaces of the inner ring are coated – standard layer.

**VL2076** External surfaces of the inner ring are coated – advanced layer.

Hybrid bearings have rings made of bearing steel and rolling elements made of bearing grade silicon nitride ( $\text{Si}_3\text{N}_4$ ), which make the bearings electrically insulating.

## Bearing features

Silicon nitride rolling elements can extend bearing service life by offering enhanced bearing performance, even under difficult operating conditions. When compared to same-sized bearings with steel rolling elements, the benefits of hybrid bearings include:

- **Protection from electric current damage**

Hybrid bearings are non-conductive and therefore suitable for applications such as AC and DC motors and generators, where electric currents are present.

- **Higher speed capability**

The density of a silicon nitride rolling element is 60% lower than a same-sized rolling element made of bearing steel. Lower weight and inertia translates into higher speed capability and superior behaviour during rapid starts and stops.

- **Long service life**

The lower frictional heat generated in hybrid bearings, especially at high speeds, contributes to extended bearing service life and extended relubrication intervals.

- **High wear-resistance**

Silicon nitride rolling elements have a higher degree of hardness making hybrid bearings suitable under difficult conditions and contaminated environments.

- **High bearing stiffness**

With a high modulus of elasticity, hybrid bearings offer increased bearing stiffness.

- **Reduced risk of smearing**

Even under inadequate lubrication conditions, such as high speeds and rapid accelerations, or where there is an insufficient hydrodynamic film, the risk of smearing is reduced between silicon nitride and steel surfaces. For conditions where  $\kappa < 1$ , it is common to apply  $\kappa = 1$  for hybrid bearing life calculations (Lubrication condition – the viscosity ratio,  $\kappa$ , [page 102](#)).

- **Reduced risk of false brinelling**

When subjected to vibration, hybrid bearings are significantly less susceptible to false brinelling (formation of shallow depressions in the raceways) between the silicon nitride and steel surfaces.

- **Less sensitivity to temperature gradients**

Silicon nitride rolling elements have a lower coefficient of thermal expansion, which means they are more stable over temperature gradients within the bearing and provide more accurate preload/clearance control.

## Assortment

The standard assortment of SKF hybrid bearings (fig. 1) comprises popular sizes for electric motors and generators. It includes:

- single row deep groove ball bearings
  - basic design
  - sealed design
  - XL hybrid design
- single row cylindrical roller bearings

Hybrid bearings provided in this catalogue constitute the basic SKF assortment and are only part of the total assortment. Other hybrid bearings include:

- hybrid super-precision bearings ([skf.com/super-precision](http://skf.com/super-precision))
  - hybrid super-precision angular contact ball bearings
  - hybrid super-precision cylindrical roller bearings
  - hybrid super-precision angular contact thrust ball bearings, single and double direction
- hybrid angular contact ball bearings
- hybrid stainless steel deep groove ball bearings
- bearing units incorporating hybrid bearings

For availability and detailed information, contact SKF.

## Designs and variants

### Hybrid deep groove ball bearings

Deep groove ball bearings are the most widely used bearing type, especially in electric motors. SKF hybrid deep groove ball bearings (fig. 2):

- are non-separable
- are suitable for high speeds
- accommodate radial loads and axial loads in both directions because their uninterrupted raceway grooves have a close osculation with the balls
- are manufactured to SKF Explorer bearing quality (page 7)
- are available with a bore diameter ranging from 5 to 180 mm
- with a bore diameter  $d \leq 45$  mm, are most suitable for electric motors in the power range 0,15 to 15 kW as well as for power tools and high-speed drives

SKF hybrid deep groove ball bearings in this size range are the most cost-effective solution against electrical erosion.

### Basic design bearings

- are available with a bore diameter  $d \geq 10$  mm

#### ⚠ WARNING

Seals made of FKM (fluoro rubber) exposed to an open flame or temperatures above 300 °C (570 °F) are a health and environmental hazard! They remain dangerous even after they have cooled.

Read and follow the safety precautions on page 197.

### Sealed bearings

- use the same seals as described under *Capped bearings*, page 242
- are lubricated for the life of the bearing and should not be washed or relubricated
- are virtually maintenance-free

When capped bearings must operate under certain conditions, such as very high speeds or high temperatures, grease may appear between the inner ring and capping device. For bearing arrangements where this would be detrimental, appropriate actions should be taken.

## 21 Hybrid bearings

### Greases for sealed bearings

The standard grease, suitable for most common operating conditions of electric motors and generators, is indicated by the designation suffix WT ([table 3, page 245](#)).

For additional information about greases, refer to *Selecting a suitable grease*, [page 116](#).

### Grease life

The estimated grease life is typically at least twice as long as for same-sized bearings with steel balls (*Grease life for capped bearings*, [page 246](#)).

### XL hybrid bearings

- are identified by the designation suffix VA970
- are designed to meet the application requirements for electric generators in larger wind turbines
- are available for the most commonly used generator sizes ([product table, page 1050](#))

## Hybrid cylindrical roller bearings

- are separable
- are suitable for high speeds
- accommodate heavy radial loads
- accommodate axial displacement ([fig. 4](#))
- are commonly used in electric motors, especially traction motors, and in applications running under severe operating conditions

### Basic design bearings

The NU design cylindrical roller bearing, which has two integral flanges on the outer ring and no flanges on the inner ring, is the standard basic design for hybrid cylindrical roller bearings ([fig. 3](#)).

## Hybrid bearings with special steel rings and coatings

For specific application requirements, hybrid bearings can be customized:

- bearing rings stabilized for temperatures  $\leq 300\text{ }^{\circ}\text{C}$  (570 °F)
- bearing rings made of through-hardened stainless steel for enhanced corrosion and wear-resistance and with good high-temperature properties
- bearing rings made of through-hardened stainless steel for cryogenic temperatures
- bearing rings made of high-temperature tool steel
- ring coating with zinc chromate or thin dense chromium for corrosion protection
- ring coating based on molybdenum for low friction, especially in vacuum or gas applications

For availability and detailed information, contact SKF.

## Cages

SKF hybrid deep groove ball bearings are fitted with one of the following cages:

- a stamped steel cage, riveted, ball centred (no designation suffix)
- a glass fibre reinforced PA66 cage, snap-type, ball centred (designation suffix TN9)
- a glass fibre reinforced PEEK cage, snap-type, ball centred (designation suffix TNH)
- a machined brass cage, riveted, ball centred (designation suffix M)

For additional information, refer to *Cages*, [page 249](#).

SKF hybrid cylindrical roller bearings are fitted with one of the following cages:

- a glass fibre reinforced PA66 cage, window-type, roller centred (designation suffix P)
- a glass fibre reinforced PEEK cage, window-type, roller centred (designation suffix PH)
- a machined brass cage, riveted, roller centred (designation suffix M)
- a machined brass cage, window-type, inner or outer ring centred (depending on bearing design) (designation suffix ML)

For additional information, refer to *Cages*, [page 502](#).

When used at high temperatures, some lubricants can have a detrimental effect on polyamide cages. For additional information about the suitability of cages, refer to *Cages*, [page 187](#).

## Loads

For recommendations about minimum load, axial load carrying capacity and equivalent bearing loads, refer to *Loads* of the relevant standard bearing:

- *Deep groove ball bearings*, [page 254](#)
- *Cylindrical roller bearings*, [page 509](#)

The required hybrid bearing specific values and factors are listed in the relevant product tables:

- *Hybrid deep groove ball bearings*, [page 1050](#)
  - basic static load rating  $C_0$
  - calculation factors  $f_0$  and  $k_r$
- *Hybrid cylindrical roller bearings*, [page 1056](#)
  - calculation factor  $k_r$
  - reference speed

## Axial preload

To provide low noise and high-speed operation, typically an axial preload to a bearing arrangement comprising two hybrid deep groove ball bearings is applied. Axial preload can be applied with spring washers, as described under *Preloading with springs*, [page 186](#).

## Temperature limits

The permissible operating temperature for hybrid bearings can be limited by:

- the dimensional stability of the bearing rings
- the cage
- the seals
- the lubricant

Where temperatures outside the permissible range are expected, contact SKF.

### Bearing rings

The rings of SKF hybrid bearings are heat stabilized up to at least:

- 120 °C (250 °F) for basic design hybrid deep groove ball bearings
- 150 °C (300 °F) for hybrid cylindrical roller bearings and XL hybrid deep groove ball bearings

On request, SKF can supply hybrid bearings with rings stabilized for operating temperatures up to 300 °C (570 °F).

### Cages

Steel, brass or PEEK cages can be used at the same operating temperatures as the bearing rings of standard hybrid bearings. For temperature limits of other polymer cages, refer to *Polymer cages*, [page 188](#).

### Seals

The permissible operating temperature for seals depends on the seal material:

- NBR: –40 to +100 °C (–40 to +210 °F)  
Temperatures up to 120 °C (250 °F) can be tolerated for brief periods.
- FKM: –30 to +200 °C (–20 to +390 °F)  
Temperatures up to 230 °C (445 °F) can be tolerated for brief periods.

Typically, temperature peaks are at the seal lip.

### Lubricants

Temperature limits for the grease used in sealed SKF hybrid deep groove ball bearings are provided in [table 3, page 116](#). For temperature limits of other SKF greases, refer to *Selecting a suitable SKF grease*, [page 116](#).

When using lubricants not supplied by SKF, temperature limits should be evaluated according to the SKF traffic light concept ([page 117](#)).

## Permissible speed

The speed ratings in the product tables (*Hybrid deep groove ball bearings*, [page 1050](#) and *Hybrid cylindrical roller bearings*, [page 1056](#)) indicate:

- the **reference speed**, which enables a quick assessment of the speed capabilities from a thermal frame of reference
- the **limiting speed**, which is a mechanical limit that should not be exceeded unless the bearing design and the application are adapted for higher speeds

For additional information, refer to *Operating temperature and speed*, [page 129](#).

SKF recommends oil lubrication for bearings with a ring centred cage (designation suffix ML). When these bearings are grease lubricated, the  $nd_m$  value is limited to  $\leq 250\,000$  mm/min.

where

$d_m$  = bearing mean diameter [mm]  
= 0,5 (d + D)

n = rotational speed [r/min]

# Designation system

Refer to *Designation system* of the relevant standard bearing:

- single row deep groove ball bearings, [page 258](#)
- single row cylindrical roller bearings, [page 514](#)

Additional designation suffixes used with SKF hybrid bearings are explained in the following.

- C3P** Displaced clearance range comprising the upper half of the C3 plus the lower half of the C4 clearance range
- F1** Grease fill 10–15% of the free space in the bearing
- HC5** Rolling elements made of silicon nitride
- S0** Bearing rings heat stabilized for operating temperatures  $\leq 150\text{ °C}$  (300 °F)
- VA970** Special design deep groove ball bearing for wind turbine generators
- VC444** Bearing rings made of high nitrogen steel

NoWear is a wear-resistant carbon coating that can be applied to the rolling elements and inner ring raceway(s) of a bearing (designation suffix L7DA) or only the rolling elements (designation suffix L5DA) (fig. 1).

A physical vapour deposition process applies the wear-resistant carbon coating. Thickness of the coating ranges from 1 to 3 µm, depending on the size of the bearing. The hardness of the coating is 1 200 HV10.

NoWear coated bearing surfaces retain the toughness of the underlying material while adopting the hardness, improved friction properties and wear-resistance of the coating.

During the running-in period, minute amounts of the coating material are transferred to the counter-surfaces. This coating reduces friction and improves resistance against wear and smearing, even in bearings where only the rolling elements are coated.

### Bearing features

- Long service life
- Withstand severe operating conditions
  - increased risk of smearing
  - insufficient lubricating film
  - sudden load variations
  - light loads
  - rapid speed changes
  - vibration and oscillations

### Applications

NoWear coated bearings may provide new possibilities for existing applications operating under severe conditions. They can provide new design possibilities while requiring no major design changes. Typical applications

where NoWear coated bearings are used include:

- paper machines
- marine and offshore applications
- fans
- compressors
- hydraulic pumps
- gearboxes
- hydraulic motors

NoWear coated bearings are not intended for vacuum or other completely dry running applications. The coating does not act as a barrier against oxygen and is therefore not recommended as a corrosion inhibitor.

# Designs and variants

The most commonly used NoWear coated bearings have a coating on only the rolling elements (designation suffix L5DA). They are recommended for applications where the bearing load is light to normal, or where vibration and oscillating movements occur.

NoWear coated bearings that have the inner ring raceway(s) and rolling elements coated (designation suffix L7DA) are recommended for any of the following operating conditions:

- abrasive contaminants that can cause premature wear
- heavy loads
- unusual lubrication conditions such as bearings lubricated by the process media

Most SKF rolling bearings can be supplied as NoWear coated bearings. For variants not listed in [table 1](#), contact SKF.

## Cages

Refer to *Cages* in the relevant product section of the standard bearing.

## Bearing data

### Dimension standards, tolerances, internal clearance, permissible misalignment

Refer to *Bearing data* in the relevant product section of the standard bearing.

## Bearing service life

The extended bearing service life that NoWear can provide in high-speed, lightly loaded applications is difficult to calculate and depends on a variety of factors. However, experience has shown a multifold improvement in bearing service life.

For greased bearings that operate at speeds near or above the permissible speed, or at high temperatures that shorten the grease life, using NoWear potentially extends relubrication intervals.

When operating under marginal lubrication conditions, NoWear can extend bearing service life.

## Loads

### Minimum load

Owing to the material combination of NoWear/steel in the contact area, the risk of smearing damage is reduced. NoWear coated bearings are recommended for applications with light loads in combination with high speeds, where smearing damage is an issue.

### Load carrying capacity, equivalent bearing loads

Refer to *Loads* in the relevant product section of the standard bearing.

## Temperature limits

For temperature limits of the bearing, refer to *Temperature limits* in the relevant product section of the standard bearing.

The NoWear coating withstands temperatures up to 350 °C (660 °F).

## Lubrication

In general, the same lubrication guidelines are valid for NoWear coated bearings as for standard bearings (*Lubrication*, [page 110](#)). However, NoWear coated bearings can operate reliably even where adequate surface separation cannot be achieved. NoWear acts as a protective layer and may reduce the need for EP and AW additives in the lubricant.

## Designation system

Refer to *Designation system* in the relevant product section of the standard bearing.

The designation suffixes used to identify NoWear coated bearings are:

**L5DA** Coated rolling elements

**L7DA** Coated rolling elements and inner ring raceway(s)

## Permissible speed

Refer to *Permissible speed* in the relevant product section of the standard bearing.

Adapter sleeves are the most commonly used components for locating bearings with a tapered bore onto a cylindrical seat as they can be used on (fig. 1):

- plain shafts
- stepped shafts

They are easy to install and require no additional location on the shaft:

- When used on plain shafts, the bearing can be located at any position on the shaft.
- When used on stepped shafts together with an L-shaped spacer ring, the bearing can be accurately positioned axially, thereby facilitating bearing mounting and dismounting.

# Designs and variants

SKF supplies:

- metric adapter sleeves
  - with a metric bore
  - with an inch bore

These sleeves are not listed in this catalogue, but can be found online at [skf.com/go/17000-23-3](http://skf.com/go/17000-23-3).

- inch adapter sleeves

Inch sleeves are coated with a solventless rust inhibitor.

Adapter sleeves listed in the [product tables, page 1072](#), constitute the standard SKF assortment and are only part of the complete assortment. For larger sizes (bore diameter  $\geq 1\,060$  mm) and variants not listed, contact SKF.

The sleeves are slit and are supplied complete with a lock nut and locking device ([fig. 2](#)):

- Smaller sizes have a nut and a lock washer.
- Larger sizes have a nut and a locking clip or locking plate.

Metric sleeves:

- with a bore diameter  $\leq 180$  mm (size  $\leq 40$ ) are phosphated
- with a bore diameter  $> 180$  mm are coated with a solventless rust inhibitor

# Sleeves for oil injection

- enable use of the oil injection method to mount and dismount bearings
- are equipped with the necessary oil supply ducts and distribution grooves
  - as standard for metric sleeves with a bore diameter ≥ 200 mm (size ≥ 44)
  - on request for metric sleeves with a bore diameter ≥ 140 mm to < 200 mm
  - on request for inch sleeves with a bore diameter ≥ 4 5/16 inches (size ≥ 26)
- include OH (metric) series, and OSNW and OSNP (inch) series

Thread details for the oil supply ducts and the appropriate hydraulic nut designations are listed in the [product tables, page 1072](#).

For information about oil injection equipment, refer to the catalogue *SKF Maintenance and Lubrication Products* or online at [skf.com/mapro](http://skf.com/mapro).

SKF manufactures sleeves for oil injection in four variants ([table 1](#)). Those with a designation suffix H are the SKF standard.

## Sleeves for CARB toroidal roller bearings

- are specially designed to prevent the locking device from interfering with the cage

SKF manufactures sleeves for CARB toroidal roller bearings in three variants (fig. 3):

- **Sleeves with the designation suffix E**
  - are supplied with a KMFE lock nut in place of the standard KM lock nut and MB lock washer
  - are supplied with an HME lock nut in place of the standard HM 30 or HM 31 lock nut
- **Sleeves with the designation suffix L**
  - are supplied with a KML lock nut and MBL lock washer, both with low cross-sectional height, in place of the standard KM lock nut and MB lock washer
- **Sleeves with the designation suffix TL**
  - are supplied with an HM 30 lock nut and MS 30 locking clip, both with low cross-sectional height, in place of the standard HM .. T lock nut and MB lock washer

When using CARB bearings, check that there is sufficient space on both sides of the bearing to accommodate axial displacement.

## Sleeves for sealed bearings

- are specially designed to prevent the locking device from interfering with the seals of sealed spherical roller bearings and sealed self-aligning ball bearings
- have the designation suffixes E, EL, EH, L, and TL (fig. 3 and fig. 4)

Adapter sleeve assemblies with the designation suffix EL or EH are supplied with one of the following, respectively:

- a KMFE .. L lock nut, which has a lower abutment diameter than the standard KMFE lock nut
- a KMFE .. H lock nut, which has a higher abutment diameter than the standard KMFE lock nut

Withdrawal  
sleeves

# 24 Withdrawal sleeves

Withdrawal sleeves are slit tapered sleeves ([fig. 1](#)), which can be used to mount bearings with a tapered bore onto a cylindrical seat of stepped shafts ([fig. 2](#)). The sleeves are pressed into the bore of the bearing inner ring, which abuts a shaft shoulder or similar fixed component. They are located on the shaft by a nut or an end plate.

The standard assortment of SKF withdrawal sleeves is available online at [skf.com/go/17000-24-1](https://skf.com/go/17000-24-1) and comprises:

- basic design sleeves ([fig. 1](#))
- sleeves for oil injection ([fig. 3](#))
- sleeves for shaft diameters up to 1 000 mm

Withdrawal sleeves are not listed in this catalogue. Comprehensive information about SKF withdrawal sleeves is available online at [skf.com/go/17000-24](https://skf.com/go/17000-24).

# 25 Lock nuts

Lock nuts are used to locate bearings onto a shaft. Additionally, they can be used to mount bearings with a tapered bore onto tapered shaft seats and adapter sleeves, and to dismount bearings from withdrawal sleeves. Lock nuts are also frequently used to secure gears, belt pulleys and other machine components.

Lock nuts have to be secured to prevent unintentional loosening by:

- a locking device that engages a keyway in the shaft or key slot in the adapter sleeve, or
- a locking mechanism integrated in the nut

When choosing or replacing a lock nut, there are a number of factors that should be taken into consideration. They include, but are not limited to:

- Space – axial and radial
- Shaft rotation – one or both directions
- Axial loads
- Dynamic behaviour of the application
- Cost and downtime of machining keyways in shafts vs. other locking methods
- Ease and frequency of assembly and disassembly
- Precision

## Designs and variants

SKF lock nuts provide a variety of ways to secure the nut onto a shaft. The lock nuts listed here constitute the basic SKF assortment. Lock nuts with other locking methods can be supplied on request. For additional information, contact SKF.

The following tables provide an overview over the basic SKF assortment:

- [table 1](#) for SKF industrial lock nuts
- [table 2, page 1092](#) for SKF precision lock nuts

Lock nuts with integral locking reduce the cost of the shaft as no keyway is required. Installation is quicker and easier because no separate locking device is necessary. However, the loosening torque of these lock nuts requires more attention. For information on loosening torque, refer to **Product data, page 1098**.

# Lock nuts requiring a keyway

## KM, KML and HM .. T metric lock nuts

KM and KML lock nuts (fig. 1):

- have metric threads
- are designed to be used with lock washers
- have four equally-spaced slots located around their circumference to accommodate a hook or impact spanner (fig. 2)
- are also referred to as shaft or withdrawal nuts
- are available for thread M 10x0,75 to M 200x3 (sizes 0 to 40)
- can be locked with either the MB lock washer (fig. 3) or with a stronger, MB .. A lock washer

KML lock nuts have a lower cross-sectional height than KM lock nuts.

HM .. T lock nuts (fig. 1):

- have metric trapezoidal threads
  - are also referred to as removal nuts
  - are available for thread Tr 210x4 to Tr 280x4 (sizes 42 to 56)
- For some sizes, no lock washer is available because these nuts are intended to dismount bearings with a tapered bore from a withdrawal sleeve.

KM, KML and HM...T lock nuts can be reused, provided they are not damaged. A new lock washer should be used each time the corresponding lock nut is installed.

## Features and benefits

- Simple, stable and reliable fastening
- Wide range of sizes
- Easy to install and remove
- Thread diameters ranging from 10 to 280 mm

## N and AN inch lock nuts

N and AN inch lock nuts (fig. 1):

- using a W lock washer (fig. 3) are available up to and including size 44 (thread diameter 8.628 in.)
- using a locking plate (fig. 4) are low-profile-series lock nuts for nominal thread diameters ranging from 9.442 to 37.410 in. (sizes N 048 to N 950)
- have four, equally spaced slots around their circumference to accommodate a hook or impact spanner (fig. 2)
- are also referred to as shaft or withdrawal nuts
- N 00 to N 14, AN 15 to AN 40 and N 44 lock nuts are normal series lock nuts commonly used together with bearings in the 12, 13, 222, 223 and 232 series up to size 23244, mounted directly to the shaft or via an adapter sleeve.
- N 022 to N 044 lock nuts are low-profile-series lock nuts commonly used together with bearings in the 230 series. They can also be used to secure other bearing types and other machine components.
- N lock nuts with a locking plate are commonly used with bearings in the 230, 231 and 232 series (sizes  $\geq 48$ ), but can also be used to retain any suitable bearing or other machine component.

N and AN lock nuts can be reused, provided they are not damaged. A new lock washer or locking plate should be used each time the corresponding lock nut is installed.

## Features and benefits

- Simple, stable and reliable fastening element
- Wide range of sizes
- Easy to install and remove
- Lock washers available for thread 0.391 to 8.628 in. (sizes 00 to 44)
- Locking plates available for thread 9.442 to 18.894 in. (sizes 048 to 096) and for thread 19.682 to 37.410 in. (sizes 500 to 950)

These lock nuts are not listed in this catalogue, but can be found online at [skf.com/go/17000-25-8](http://skf.com/go/17000-25-8).

## HM and HME metric lock nuts

HM and HME lock nuts (fig. 5):

- have metric trapezoidal threads
- have eight equally-spaced slots located around their circumference to accommodate an impact spanner (fig. 6)
- are located on the shaft by MS locking clips (fig. 7)

When compared to HM lock nuts, HME lock nuts have a recessed side face to accommodate axial displacement of CARB toroidal roller bearings (fig. 8).

HM and HME lock nuts can be reused, provided they are not damaged. A new locking clip should be used each time the corresponding lock nut is reinstalled.

### Features and benefits

- Simple, stable and reliable fastening element
- Wide range of sizes
- Easy to install and remove
- Available for thread Tr 220x4 to Tr 1120x8 (sizes 44 to /1120)

### The locking principles

Lock washers, locking clips and locking plates are simple, stable and reliable fastening elements.

- Lock washers (fig. 3, page 1093) engage a keyway in a shaft, or adapter sleeve thread. The washer locks the nut in position when one of the washer tabs is bent into one of the slots on the nut's outside diameter (fig. 9).
- Locking plates (fig. 4, page 1093) engage a keyway in a shaft or adapter sleeve and are attached to the side face of the nut by two bolts secured with locking wire. A locking plate consists of a plate, two hexagonal head bolts with drilled heads and lock wire to secure them (fig. 10).
- Locking clips (fig. 7) engage a keyway in a shaft or adapter sleeve and one of the slots in the outside diameter of the lock nut. Locking clips are attached to the nut by a bolt (fig. 11).

# Lock nuts with integral locking

Lock nuts with integral locking reduce the cost of the shaft as no keyway is required. Installation is quicker and easier because no separate locking device is necessary.

## KMFE lock nuts

KMFE lock nuts (fig. 12):

- are designed to locate CARB toroidal roller bearings, sealed spherical roller bearings and sealed self-aligning ball bearings axially on a shaft
- have appropriate contact faces for the intended bearings
- are available for thread M 20x1 to M 200x3 (sizes 4 to 40)

KMFE lock nuts should not be used on shafts with a keyway. They should only be used with special adapter sleeves with a narrow slot. Damage to the nut can result if the grub screw aligns with a keyway or wide slot. KMFE lock nuts can be reused, provided they are not damaged.

## Features and benefits

- Maximum axial run-out between the locating face and thread: 0,02 to 0,03 mm
- No keyway required
- Simple to install
- Simple and robust locking
- Reusable
- Appropriate contact faces for intended bearings
- Equipped with visual marks for the use of tightening angles

## KMK lock nuts

KMK lock nuts (fig. 13):

- are intended to locate radial bearings in less demanding applications
- are available for thread M 10x0,75 to M 100x2 (sizes 0 to 20)

KMK lock nuts should not be used on shafts with keyways or adapter sleeves with key slots. Damage to the locking device can result if it aligns with a keyway or slot. KMK lock nuts can be reused, provided they are not damaged.

These lock nuts are not listed in this catalogue, but can be found online at [skf.com/go/17000-25-5](http://skf.com/go/17000-25-5).

## The locking principle

Lock nuts with integral locking are locked by friction. The friction is sufficient to lock the nut in place.

KMFE lock nuts have an integral grub (set) screw, to lock the nut in place. When the grub screw is tightened, it causes the nut thread to deform and press against the shaft or sleeve thread (fig. 14).

KMK have a threaded steel insert in their bore. The threads on the insert match the lock nut threads. The insert acts as a pressure plate when a grub screw, which runs through the body of the lock nut, is tightened (fig. 15).

# Precision lock nuts with locking pins

KMT and KMTA lock nuts are intended for applications where high precision, simple assembly and reliable locking are required<sup>1)</sup>. The three equally-spaced locking pins enable these lock nuts to be accurately positioned at right angles to the shaft. However, they can also be adjusted to compensate for slight angular deviations of adjacent components.

KMT lock nuts (fig. 16):

- are available for thread M 10x0,75 to M 200x3 (sizes 0 to 40)
- are available on request for thread Tr 220x4 to Tr 420x5 (sizes 44 to 84)

KMTA lock nuts (fig. 17):

- are available for thread M 25x1,5 to M 200x3 (sizes 5 to 40)
- have a cylindrical outside surface and, for some sizes, a different thread pitch than KMT lock nuts
- are intended primarily for applications where space is limited and the cylindrical outside surface can be used as an element of a gap-type seal

## Features and benefits

- Maximum axial run-out between the locating face and thread (sizes  $\leq 40$ ): 0,005 mm
- Adjustable to compensate for slight angular deviations (fig. 18)
- Fine thread pitch
- Withstands high axial loads
- Reliable, effective locking mechanism
- Simple installation and removal
- No keyway required<sup>1)</sup>
- Reusable
- Designed for frequent installation and removal

<sup>1)</sup> KMT and KMTA lock nuts should not be used on shafts with keyways in the thread or adapter sleeves. Damage to the locking pins can result if they align with either.

Fig. 16

## The locking principle

KMT and KMTA series precision lock nuts have three locking pins equally spaced around their circumference (fig. 19 to fig. 21) that can be tightened with grub screws to lock the nut onto the shaft. The end face of each pin is machined to match the shaft thread. The holes for the locking pins and grub screws are drilled with their axis parallel to the loaded flanks of the shaft thread (fig. 22). The locking screws, when tightened to the recommended torque, provide sufficient friction between the ends of the pins and the unloaded thread flanks to prevent the nut from loosening under normal operating conditions (Loosening torque, page 1098). Because the locking pins are tightened against the unloaded flanks of the shaft thread, they are not subjected to any application loads imposed on the nut.

## Precision lock nuts with axial locking screws

KMD lock nuts (fig. 23) were designed specifically for screw compressors but can be used in other applications where high precision, simple assembly and reliable locking are required. Once the four locking screws are tightened, the lock nut will be accurately positioned at right angles to the shaft thread. The locking screws, when tightened to the recommended tightening torque, preload the lock nut and shaft threads and generate sufficient friction to prevent the nut from loosening under normal operating conditions. The locking screws do not carry any part of the supported load in service.

KMD lock nuts are available for thread M 20x1 to M 105x2 (sizes 4 to 21).

## Features and benefits

- Maximum axial run-out between the locating face and thread: 0,005 mm
- Adjustable for precise axial positioning
- Effective locking prevents the nut from loosening under normal operating conditions
- Simple installation and removal
- No keyway required
- Reusable
- Designed for frequent installation and removal

These lock nuts are not listed in this catalogue, but can be found online at [skf.com/go/17000-25-6](http://skf.com/go/17000-25-6).

## The locking principle

KMD lock nuts are locked with axial locking screws (fig. 24). The front of the lock nut locates the component on the shaft. The rear is tightened against the unloaded flanks of the shaft thread by axial locking screws, creating sufficient friction to prevent the lock nut from loosening under normal operating conditions.

The friction, and therefore the loosening torque, varies as a result of the accuracy of the tightening torque of the grub (set) screw, the surface finish of the shaft (sleeve) thread, the amount of lubricant on the thread, etc. The lock nuts should be properly mounted to threads that are dry or only have a minimum amount of lubricant on them.<br><br>KMFE and KMK lock nuts provide sufficient locking for intended bearing applications. |

KMT and KMTA lock nuts are locked on the shaft (sleeve) by friction. The friction, and therefore the loosening torque, varies as a result of the accuracy of the tightening torque of the grub screw, the surface finish of the shaft thread, the amount of lubricant on the thread, etc. KMT and KMTA lock nuts should be properly mounted to threads that are dry or only have a minimum amount of lubricant on them.

Providing that they are properly mounted to a dry or minimally lubricated thread, experience has shown that SKF KMT and KMTA lock nuts have sufficient locking for typical super-precision and general rolling bearing applications.

# Installation and removal

## Lock nuts requiring a keyway

Lock nuts requiring a keyway are easy to install. Each nut is provided with four equally-spaced slots around their circumference to accommodate a hook or impact spanner. The designations of the associated spanners are listed in the relevant product tables.

Lock nuts requiring a keyway can be reused, provided they are not damaged. A new lock washer, locking clip or locking plate should be used each time the corresponding lock nut is reinstalled.

## Using lock nuts with lock washer to lock a bearing

### Mounting bearings and components on a cylindrical shaft

- 1 Put the bearing in place onto the cylindrical shaft.
- 2 Go ahead with step 5 below Locking the bearing.

### Mounting bearings on an adapter sleeve or tapered seat

- 1 Slide the bearing onto the adapter sleeve or tapered seat.
- 2 With the chamfer facing the bearing, screw the nut (without the lock washer) onto the adapter sleeve or shaft thread (fig. 25).
- 3 Tighten the nut with a hook or impact spanner until the correct clearance in the bearing is obtained (fig. 26).
- 4 Remove the nut. Go to step 5.

### Locking the bearing

- 5 Slide the lock washer onto the thread until it touches the bearing. With the chamfer facing the bearing, screw the lock nut into place (fig. 27).
- 6 Tighten the nut firmly against the lock washer and bearing with a hook or impact spanner, making sure to not over tighten the nut. For bearings on adapter sleeves or tapered shafts, make sure that the bearing is not driven up any further on its seat.
- 7 Lock the nut in place by bending one of the lock washer tabs down into one of the slots on the nut (fig. 28). Do not bend the tab to the bottom of the slot.

### Using lock nuts with locking clips to lock a bearing

- 1 With the bearing or component in position, screw the lock nut into place.
- 2 Tighten the nut against the bearing or component with an impact spanner (fig. 29), aligning one of the slots in its outside diameter with the keyway in the shaft thread and making sure to not over tighten it.
- 3 Place the spring washer and locking clip onto the attachment bolt.
- 4 Position the locking clip in the keyway in the shaft thread, and the slot in the nut outside diameter, and secure with the attachment bolt and spring washer. Align the bolt with one of the threaded holes on the side face of the lock nut.
- 5 Tighten the bolt with an appropriate wrench (fig. 30).

## Lock nuts with integral locking

Lock nuts with integral locking are easy to install. Each nut is provided with four equally spaced slots around its circumference to accommodate a hook spanner. The designations of the associated spanners are listed in the [product table, page 1112](#).

Lock nuts with integral locking can be reused, provided they are not damaged.

### Mounting

#### Mounting bearings on a tapered seat or special adapter sleeve

- 1 Slide the bearing onto its tapered seat.
- 2 With the contact face toward the bearing, screw the nut onto the shaft.
- 3 Tighten the nut with a hook or impact spanner, until the required internal clearance in the bearing is obtained.
- 4 Tighten the grub (set) screw to the torque value listed in the [product table](#).

### Locking bearings on a cylindrical seat

- 1 With the bearing in position, screw the lock nut into place.
- 2 Tighten the nut against the bearing with a hook spanner, making sure to not over tighten it.
- 3 Tighten the grub (set) screw to the torque value listed in the [product table](#).

### Dismounting

- 1 To remove the lock nut, loosen the grub screw. Even when the grub screw is removed, the lock nut will generate a limited locking torque.
- 2 In order to completely release the locking system and facilitate the reuse of the lock nut, tap the areas near the grub screw with a hammer and soft bar. Do not damage the threaded bores for the grub screw.
- 3 Unscrew the lock nut using a hook spanner.

## Precision lock nuts with locking pins

KMT precision lock nuts have slots around their circumference to accommodate a hook or impact spanner (fig. 19, page 1097, and fig. 20, page 1097). The designations of the associated spanners are listed in the [product table, page 1114](#). KMT precision lock nuts with a thread  $\leq 75$  mm (sizes  $\leq 15$ ) have additionally to the slots two opposed flats to accommodate a spanner. Those lock nuts with a thread  $\geq 80$  mm (sizes  $\geq 16$ ) have six slots and no flats.

KMTA precision lock nuts have holes around their circumference and in one side face (fig. 21, page 1097). They can be tightened with a pin wrench or a pin-type face spanner. Associated spanners in accordance with DIN 1810 are listed in the [product table, page 1116](#).

Precision lock nuts with locking pins are designed for frequent installation and removal, provided they are not damaged.

### Installation

- 1 With the bearing in position, screw the lock nut into place.
- 2 Tighten the nut with a hook or impact spanner making sure not to over tighten it.
- 3 Tighten the grub screws carefully until the locking pins engage the shaft thread.
- 4 Tighten the grub screws alternately with a torque wrench until the recommended torque value, listed in the product tables, is achieved.

Precision lock nuts with locking pins should not be used to drive a bearing up onto a tapered seat.

### Adjustment

Precision lock nuts with locking pins are adjustable. The three equally-spaced locking pins enable these lock nuts to be accurately positioned at right angles to the shaft. However, they can also be adjusted to compensate for slight angular deviations of adjacent components.

Adjustments can be made using the following procedure (fig. 31 and fig. 32):

- 1 Loosen the grub screw(s) at the position showing the greatest deviation.
- 2 Tighten the remaining screw(s) equally.
- 3 Retighten the screw(s) that were loosened.
- 4 Check that the alignment of the nut, relative to the shaft, is currently as required.
- 5 Repeat the procedure if necessary.

### Removal

When removing precision lock nuts with locking pins, the locking pins can still engage the shaft thread even after the grub screws have been loosened. Using a rubber hammer, tap the nut lightly in the vicinity of the pins to loosen them.

**Sketch:** For example, of an industrial bearing arrangement

*For a different configuration, please add an assembly drawing with corresponding distance of the different components and orientation of the load.*

Loads

For a single bearing only:

Radial loadkN

Axial loadkN

For a shaft and bearings:

Select one of the coordinates system below the loads on the shaft.

- ☐ Cartesian coordinates
- ☐ Polar coordinates

\* Supply information for additional loads in a separate document.

☐ Peak loadkN

☐ Alternating loadkN

☐ Moment loadkN

If load and/or speed change over time, provide details of the load/speed cycle.
